

# POWER STATION ENGINEERING

(Diploma 6<sup>th</sup> SEM)

*Education for a World Stage*

Prepared by

Mr. AJAYA KUMAR BEURA

Asst. Professor

Mechanical Engineering

**NM INSTITUTE OF ENGINEERING & TECHNOLOGY  
BHUBANESWAR**

PPE  
(Power Plant Engineering)

Sources of Energy:-

① Fuels:-

Solid fuels :- Various solid fuels are wood, coal (bituminous coal, anthracite, lignite) peat wood ( $3000 - 4000 \text{ cal/kg}$ )

Liquid fuels :-

Petroleum & its derivatives (petrol, diesel, kerosene etc.).

Gaseous fuels :-

Natural gas, producer gas, blast furnace gas, coal gas etc.

*Education for a World Stage*

② Energy stored in water :-

The potential energy of water at higher level is utilized for generation of electrical energy.

Epitacal

Capital cost of hydroelectric power plant is higher but running cost is low.

### ③ Nuclear Energy :-

#### Wind Power

Wind is a renewable source of energy. Velocity of wind can be utilized to generate small amount of electrical energy.

Eg:- Water pump from deep wells.

wind turbine.

But wind energy is noisy & large area is required.

In India Only wind speed 10-15 m/s.  
Modern wind mill work at low speed 3-7 m/s.  
more efficient at 10-12 m/s.

### ④ Solar Energy :-

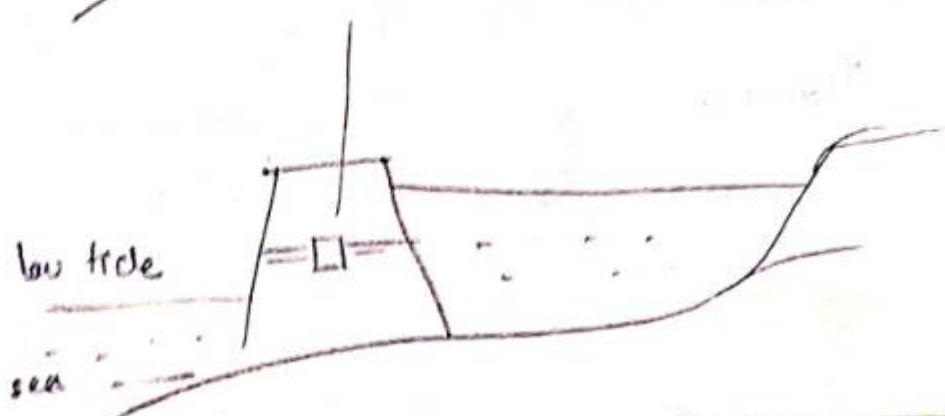

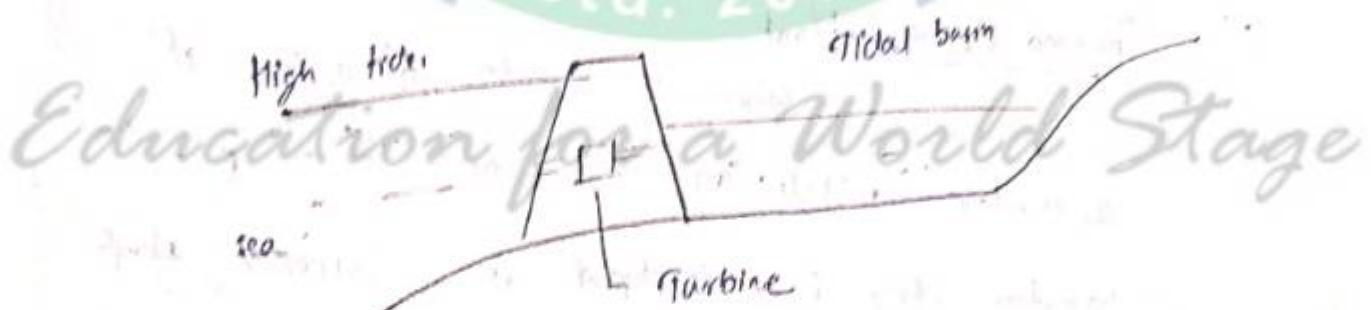

The heat energy contained in the rays of sun can be utilised.

- Electric power generation
- Solar water pumps. is used for pumping water

- iii) solar water heater used for water heating.
- iv) solar cabinet type driers for drying.
- v) solar green house.
- vi) solar kilns for drying wood etc.

Solar energy is available in the day time & can be stored in storage battery.  
 - It is free from pollution & noise.

(5) ~~Wind power~~  
 Ocean waves & tides  
 amount of energy  
 In tidal power plant total basin is used for generating  
 power.

## Advantages :-

(8)

- There is no carbon.
- Does not depends upon rain.
- Free from pollution.
- less space is required.

## Disadvantages :-

- Capital cost is high.
- Supply of power is not continuous.
- Away from load centres.

## (6) Geothermal Energy

The earth has a molten core.  
 Due to volcanic action steam vents & hot  
 springs are formed. These natural  
 steam wells is used for generation of plant.

## (7) Thermo electric Plant

when 2 junctions of a loops of  
 2 dissimilar metals are kept at diff. temp.  $\rightarrow$  an  
 electromotive force is developed.  $\therefore$  current starts  
 flowing.

## ⑧ Nuclear Energy

Heavier unstable atoms such as  $U^{235}$ ,  $Th^{232}$  and  $Pu^{239}$  (Plutonium) liberate a large amount of heat energy.

1 kg  $U^{235}$  = 4500 tonnes of high grade coal.

### Captive Power plant

It is used to provide a localised source of power to an energy user.

The plant may operate in grid parallel mode with the ability to export surplus power to the local electricity distribution network.

### Central power plant :-

It is the distribution point for campus utilities, including electricity, heat, cooling,

natural gas.

If has co-generation aspects.

It can produce 70% of campus electricity as a by product of steam production.

## Classification of Power plants

1. On the basis of fuel.

i) Steam power plant

(a) Condensing P.P.

(b) non- " "

ii) Diesel P.P.

iii) Nuclear P.P.

iv) Hydro-electric P.P.

v) Gas turbine "

2. On the basis of nature of load.

i) Base load. P.P.

ii) Peak " "

3. On the basis of location.

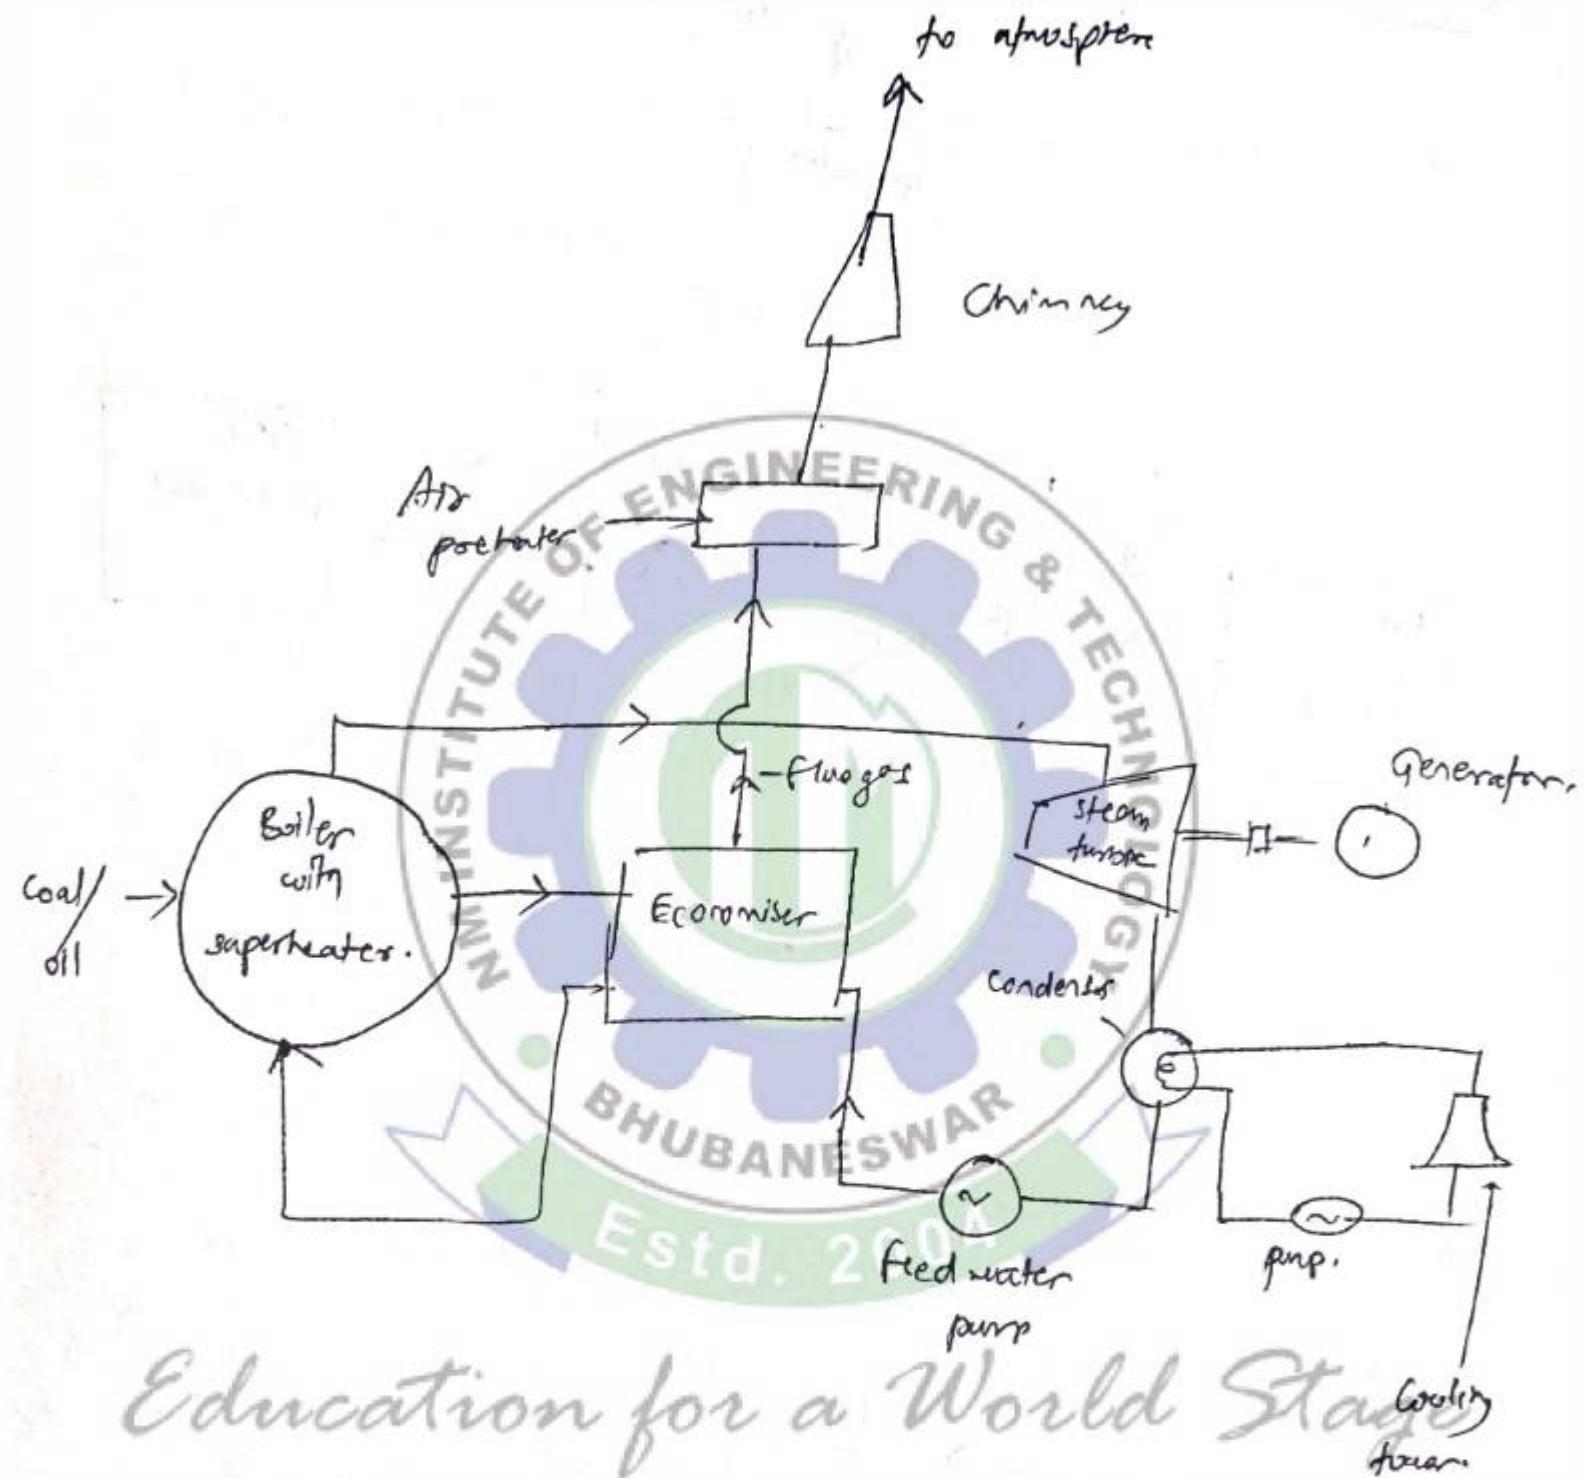

i) Central power station

ii) Isolated

4. On the basis of service

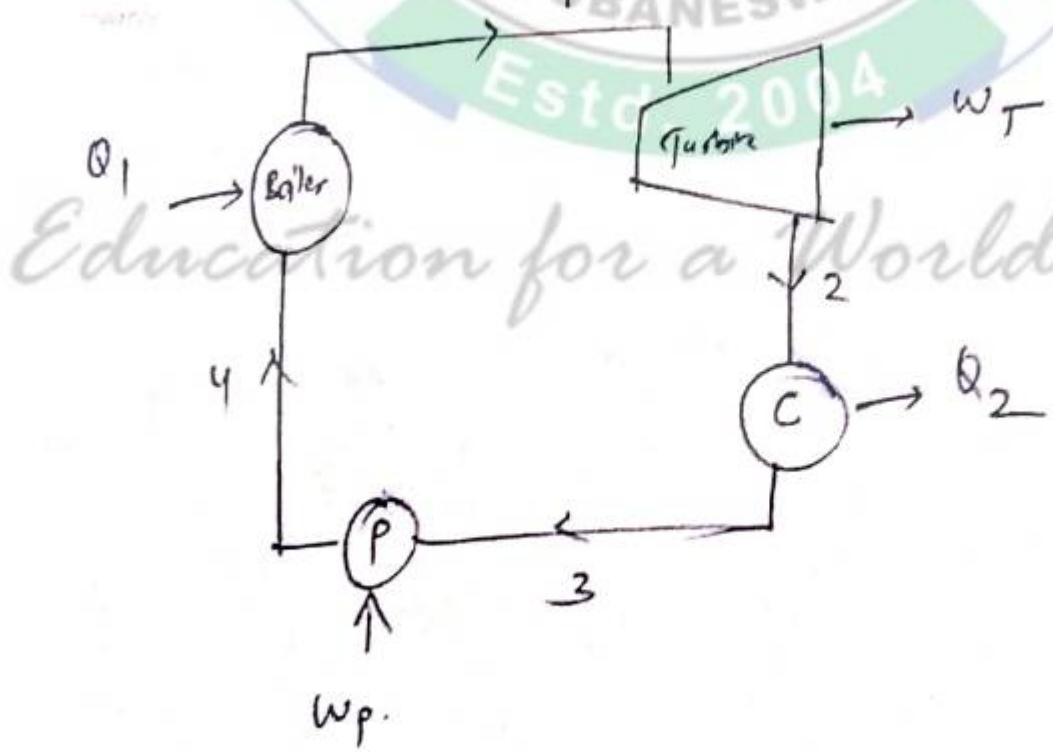

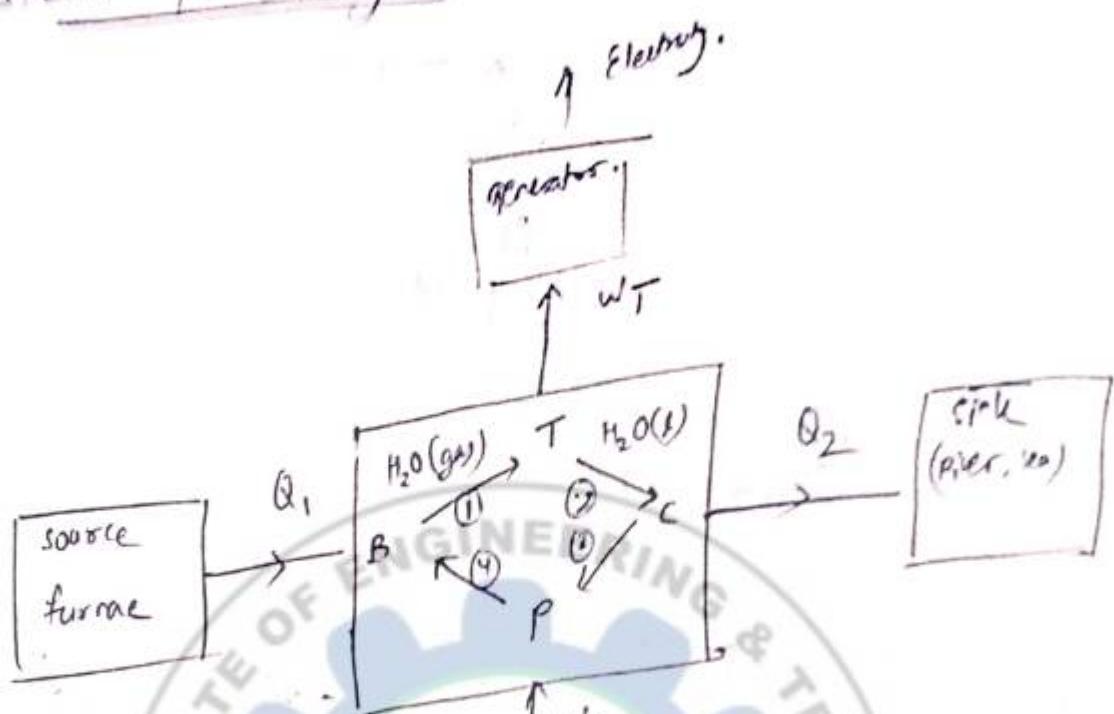

i) Stationary

ii) Locomotive

Education for a World Stage

# Steam Power Cycle

Education for a World Stage

A steam power plant continuously converts the energy stored in fuel (coal, oil, gas) into work. It ultimately turns to electricity.

The working fluid is water which is in the form of liquid or gaseous state (operation).

The energy released by burning the fuel is transferred to water in boiler (B) to generate steam at a high pr. & temp. It expands in turbine (T) to a low pr. to produce work.

The steam leaving turbine is condensed into water in condenser (C). Heat is released into sink or river water feed back to the boiler

open the water

feed back

to the boiler

Education for a World Stage

by PMP (P)

This cycle goes on repeating.

The water flow through B-T-C-P.

Internal energy is constant

$$\text{so } \oint dE = 0.$$

$$\sum Q_{\text{net}} = \sum W_{\text{net}}$$

$$Q_1 - Q_2 = W_T - W_P.$$

$Q_1$  = heat transferred to the working fluid ( $\text{kJ/kg}$ )

$Q_2$  = " rejected from "

$W_T$  = work transferred from the working fluid

$W_P$  = work " into the " "

Efficiency of steam power cycle

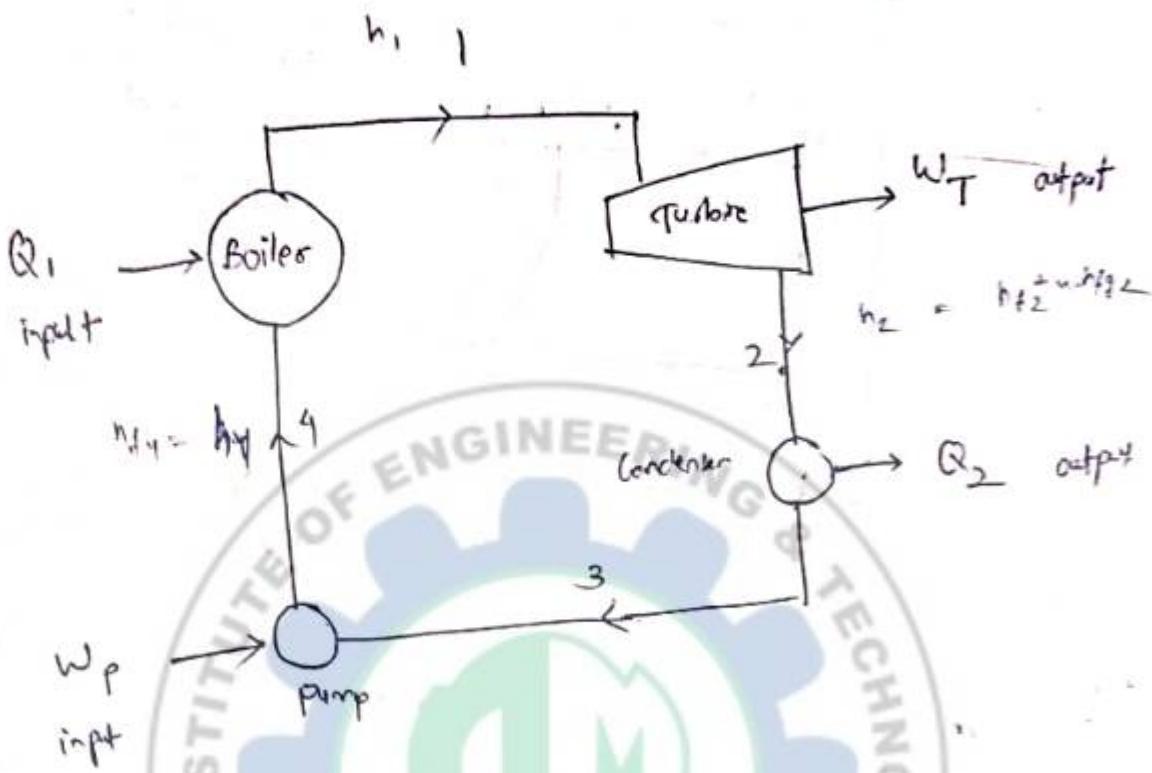

$$\eta_{\text{cycle}} = \frac{W_{\text{net}}}{Q_1}$$

$$= \frac{W_T - W_P}{Q_1}$$

$$= \frac{Q_1 - Q_2}{Q_1}$$

$$\boxed{\eta = 1 - \frac{Q_2}{Q_1}}$$

## Rankine Cycle :-

for the steam boiler it would be a reversible constant heating process. of water to form steam.

(constant vol)

for turbine reversible adiabatic expansion.

Entropy - temp. constant

heat

for condenser reversible const pressure rejection process.

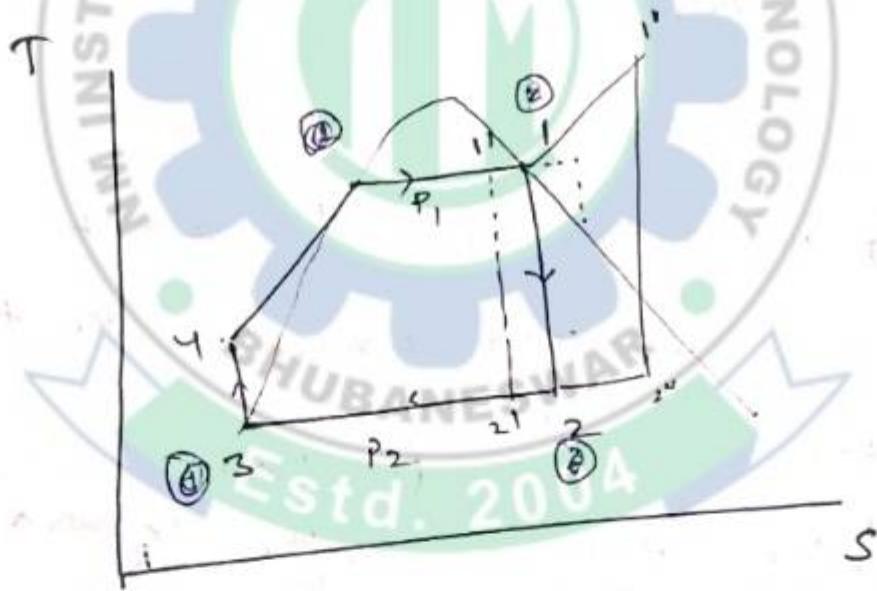

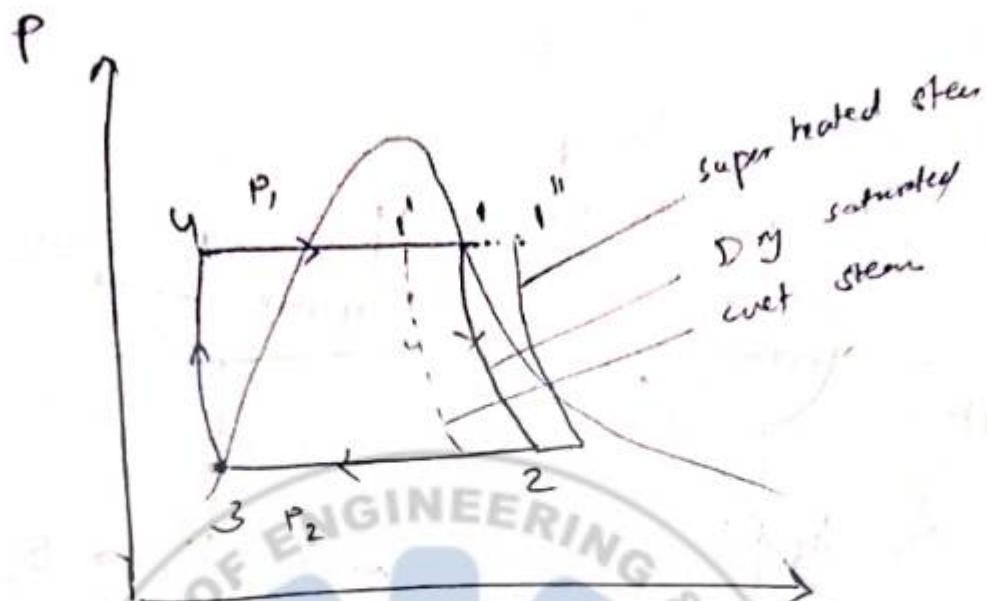

for pump the process will be

reversible adiabatic compression of the liquid

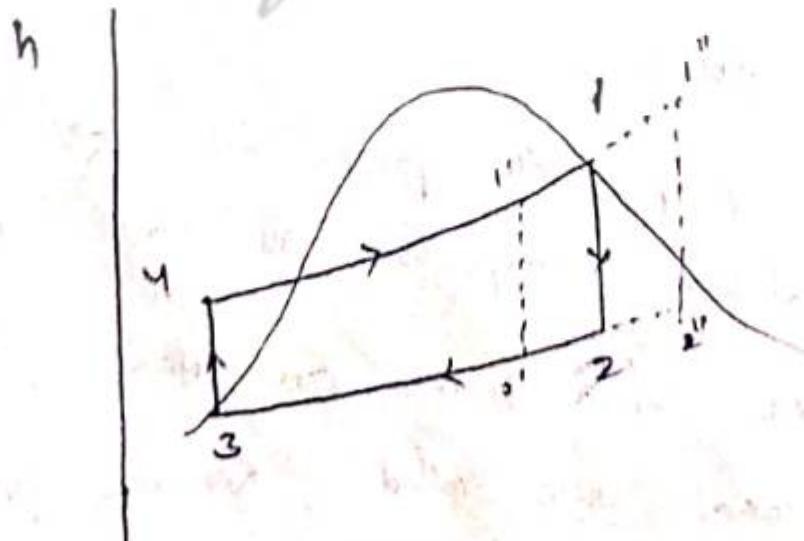

when all these four processes are ideal, the cycle

is an ideal cycle called Rankine cycle.

This is a reversible cycle.

Education for a World Stage

- process 1-2 - Reversible adiabatic expansion (Turbine)
- 2-3 - constant pr. heat transfer (condenser)
- 3-4 - Reversible adiabatic pumping process (pump)
- 4-1 - constant pr. transfer of heat (boiler)

$$\left[ \begin{array}{l} \text{Enthalpy} \\ \text{Entropy} \end{array} \right] \quad \left. \begin{array}{l} h = u + pv \\ S = \frac{dQ}{T} \end{array} \right\} \quad u = \text{internal energy.}$$

Applying steady flow energy eq<sup>n</sup>.

For Boiler

$$h_4 + Q_1 = h_1$$

$$Q_1 = h_1 - h_4$$

Turbine

$$h_1 = w_T + h_2$$

$$w_T = h_1 - h_2$$

Condenser

$$h_2 = Q_2 + h_3$$

$$Q_2 = h_2 - h_3$$

Pump

$$h_3 + w_p = h_4$$

*Education for a World Stage*

Thermal efficiency of Rankine cycle

$$\eta = \frac{W_{net}}{Q_1} = \frac{w_T - w_p}{Q_1} = \frac{(h_1 - h_2) - (h_4 - h_3)}{h_1 - h_4}$$

$$\boxed{\eta = \frac{(h_1 - h_2) - (h_4 - h_3)}{(h_1 - h_4)}}$$

As compare to turbines, the pump work is small.  
so it can be neglected.

$$\eta = \frac{h_1 - h_2}{h_1 - h_4}$$

$$\eta = \frac{h_1 - h_2}{h_1 - h_f - h_2}$$

$$\text{work Ratio} = \frac{W_{\text{net}}}{C_L} = \frac{w_T - w_p}{w_T}$$

$$= 1 - \frac{w_p}{w_T}$$

$$= 1 - \left( \frac{h_4 - h_2}{h_1 - h_2} \right)$$

*Education for a World Stage*

Specific steam consumption or  
heat rate ( $s.r$ ) =  $\frac{1}{w_{\text{net}}} \left( \frac{\text{kg}}{\text{kW.s}} \right)$

H.R Heat Rate =  $\frac{Q_1}{w_T - w_p} = \frac{1}{\eta} \left( \frac{\text{kg}}{\text{kW.s}} \right)$

## Reheat cycle

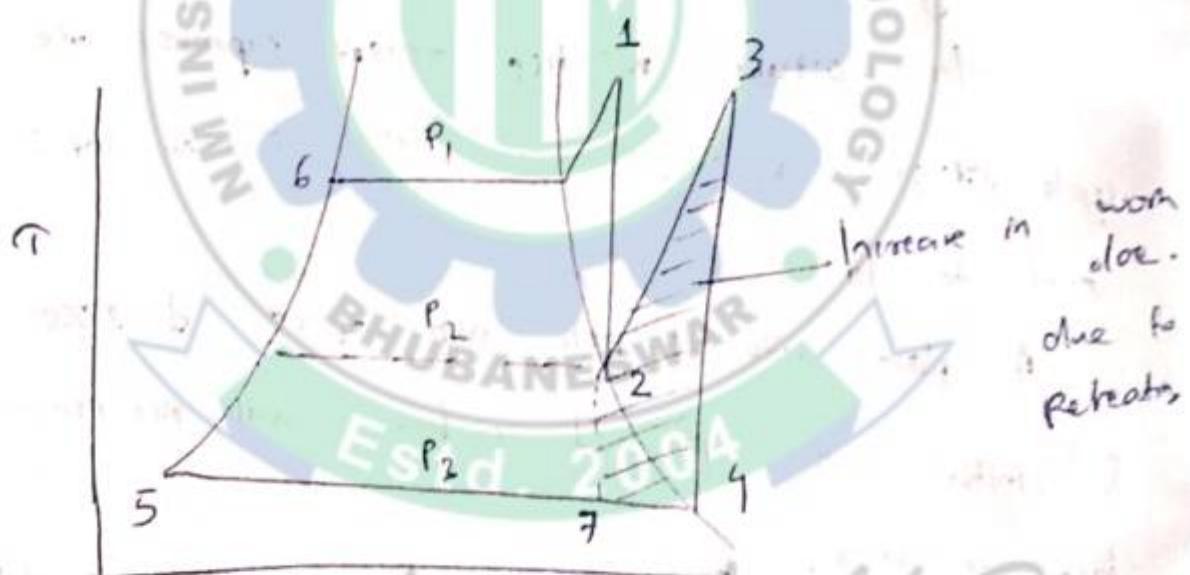

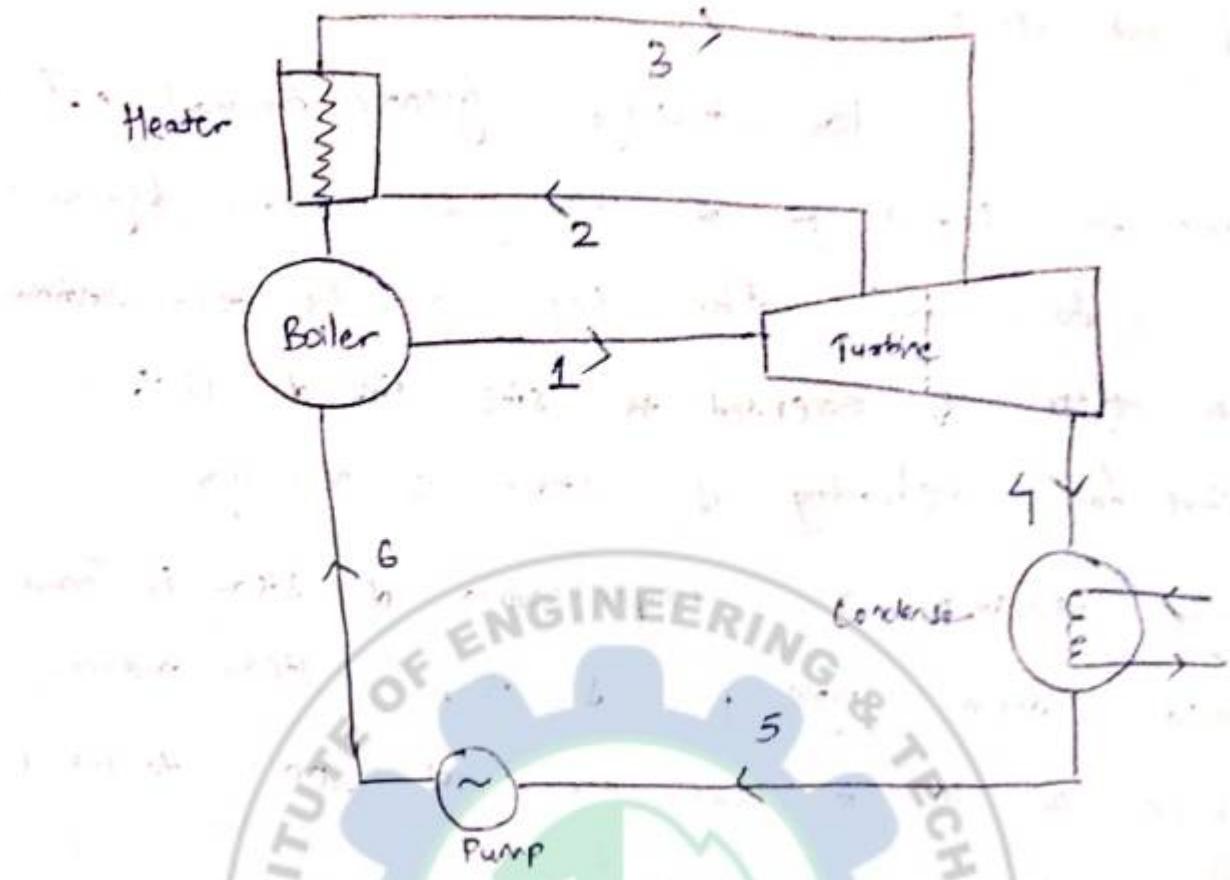

for attaining greater thermal efficiency, when the initial pr. of steam was raised beyond 42 bar, it is found that, after expansion the steam condition was wetter & exceeded the safe limit of 12%. Therefore reheating of steam is necessary.

The reheating or superheating of steam is now used when high pr. & temp. such as 100 to 250 bar and  $500^{\circ}\text{C}$  to  $600^{\circ}\text{C}$ . are employed.

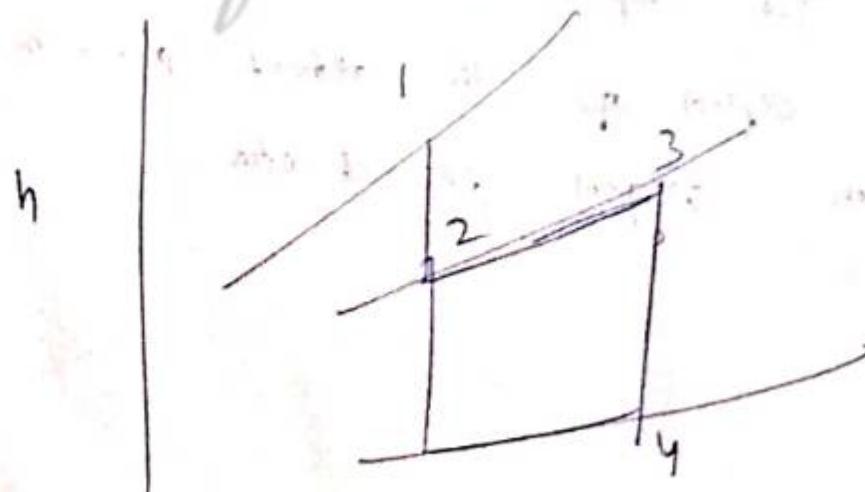

In actual practice reheat improves the cycle efficiency by 5%. The increase can be 5% to 10%.

A plant with a base load capacity of 5000 kw & initial steam pr. of 42 bar will run economically by reheating.

The improvement of thermal efficiency due to reheat depends upon the reheat pr. with respect to the original pr. of steam.

*Education for a World Stage*

$$\text{Heat supplied} = (h_1 - h_{f1}) + (h_2 - h_2)$$

$$\text{Heat rejected} = h_4 - h_{f4}$$

Work done by turbine = Heat supplied - Heat rejected

$$= (h_1 - h_{f1}) + (h_2 - h_2) - (h_4 - h_{f4})$$

$$(h_1 - h_2) + (h_2 - h_4)$$

$$\eta_{\text{thermal}} = \frac{(h_1 - h_2) + (h_2 - h_4)}{(h_1 - h_{f1}) + (h_2 - h_4)}$$

$$w_p = v_f \frac{(P_r - P_b)}{1000} \cdot k_3 / k_2$$

$$\eta = \frac{(h_1 - h_2) + (h_2 - h_4) - w_p}{(h_1 - h_{f1}) + (h_2 - h_4) - w_p}$$

*Education for a World Stage*

$$\left( \eta = \frac{h_1 - h_f}{h_1 - h_{f1}} \right)$$

$$(\because h_{f4} - h_{f2})$$

## Regenerative cycle

In Rankine cycle, the condensate, liquid is at a low temperature, which mixed with hot boiler water, irreversibly. and it results in decrease in efficiency.

So the condensate water is heated before feeding to the boiler. This heating method is called regenerative feed heating & the cycle is called regenerative cycle.

Steam is extracted from turbine at several locations as it is supplied to the regenerative heaters. Heating arrangement

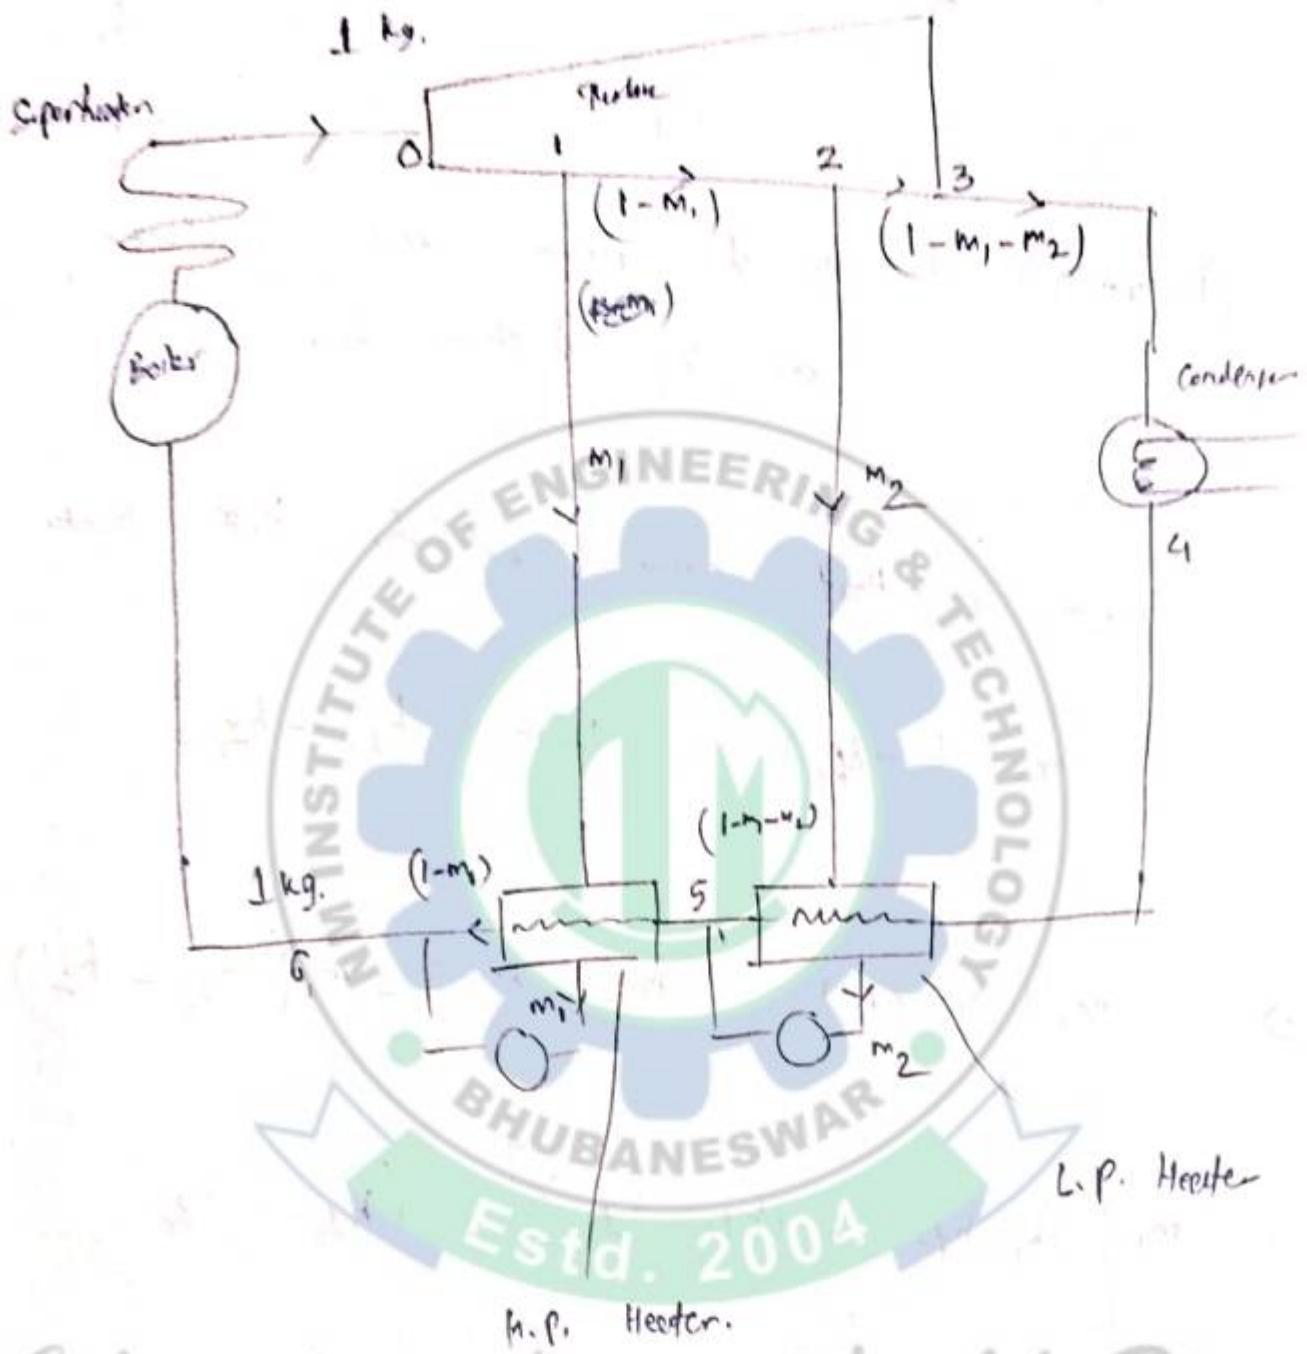

Education for World Stage

Medium capacity turbines  $\rightarrow$  3 heaters.

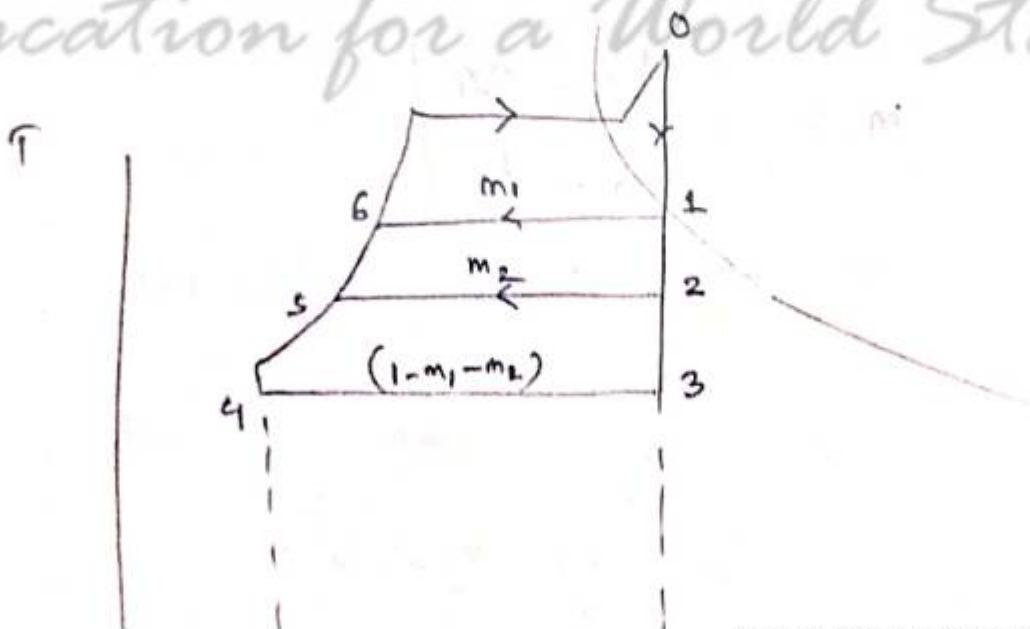

High pr. " - 5-7 "

Supercritical " - 8-9 "

The temp is kept  $50^{\circ}$  to  $60^{\circ}$  below the boiler steam.

*Education for a World Stage*

$m_1 = \text{kg of h.f.p. steam per kg of steam}$   
for

$(1-m_1-m_2) = \text{kg of steam entering condenser}$   
per kg of steam flow.

Energy or heat balance eqn for H.P. Heats.

$$m_1(h_i - h_{fg}) = (1-m_1)(h_{fg} - h_{fs})$$

$$\Rightarrow m_1(h_i - h_{fg}) = (h_{fg} - h_{fs}) - m_1(h_{fg} - h_f)$$

$$\Rightarrow m_1 \left[ (h_i - h_{fg}) + (h_{fg} - h_{fs}) \right] = (h_{fg} - h_{fs})$$

Education for a World Stage

$$\Rightarrow m_1 = \left[ \frac{h_{fg} - h_{fs}}{h_i - h_f} \right]$$

for L.P. heater.

$$m_2(h_2 - h_{fr}) = (1-m_1 - m_2)(h_{fr} - h_{f2})$$

$$\Rightarrow m_2(h_2 - h_{fr}) = (1-m_1)(h_{fr} - h_{f2}) - m_2(h_{fr} - h_{f3})$$

$$\Rightarrow m_2 \left[ (h_2 - h_{fr}) + (h_{fr} - h_{f3}) \right] = (1-m_1)(h_{fr} - h_{f3})$$

$$m_2 = \left[ \frac{(1-m_1)(h_{f3} - h_{f2})}{(h_2 - h_{f3})} \right]$$

Here pump work is neglected.  
Heat supplied =  $(h_0 - h_{fr})$

Isentropic work done =  $m_1(h_0 - h_1) + m_2(h_0 - h_2) + (1-m_1-m_2)(h_0 - h_3)$

Thermal efficiency of regenerative cycle

$$\eta = \frac{\text{Work done}}{\text{Heat supplied}}$$

Azadindar

work done by turbine

$$= (h_0 - h_1) + (1-m_1)(h_1 - h_2) + (1-m_1-m_2)(h_2 - h_3)$$

Advantages of regenerative cycle :-

1. Heating process becomes reversible.
2. thermal stress set up in boiler is minimized.
3. thermal efficiency improved.
4. Heat rate reduced.
5. Erosion & corrosion in turbine reduces.
6. small size condenser is required.

*Education for a World Stage*

Disadvantage :-

1. Plant becomes more complicated.
2. Maintenance is req.
3. large boiler is req.
4. Heaters are costly.

## Boiler Accessories :-

### Air preheater

The function of A.P.H is to increase the temp of air before it enters the furnace.

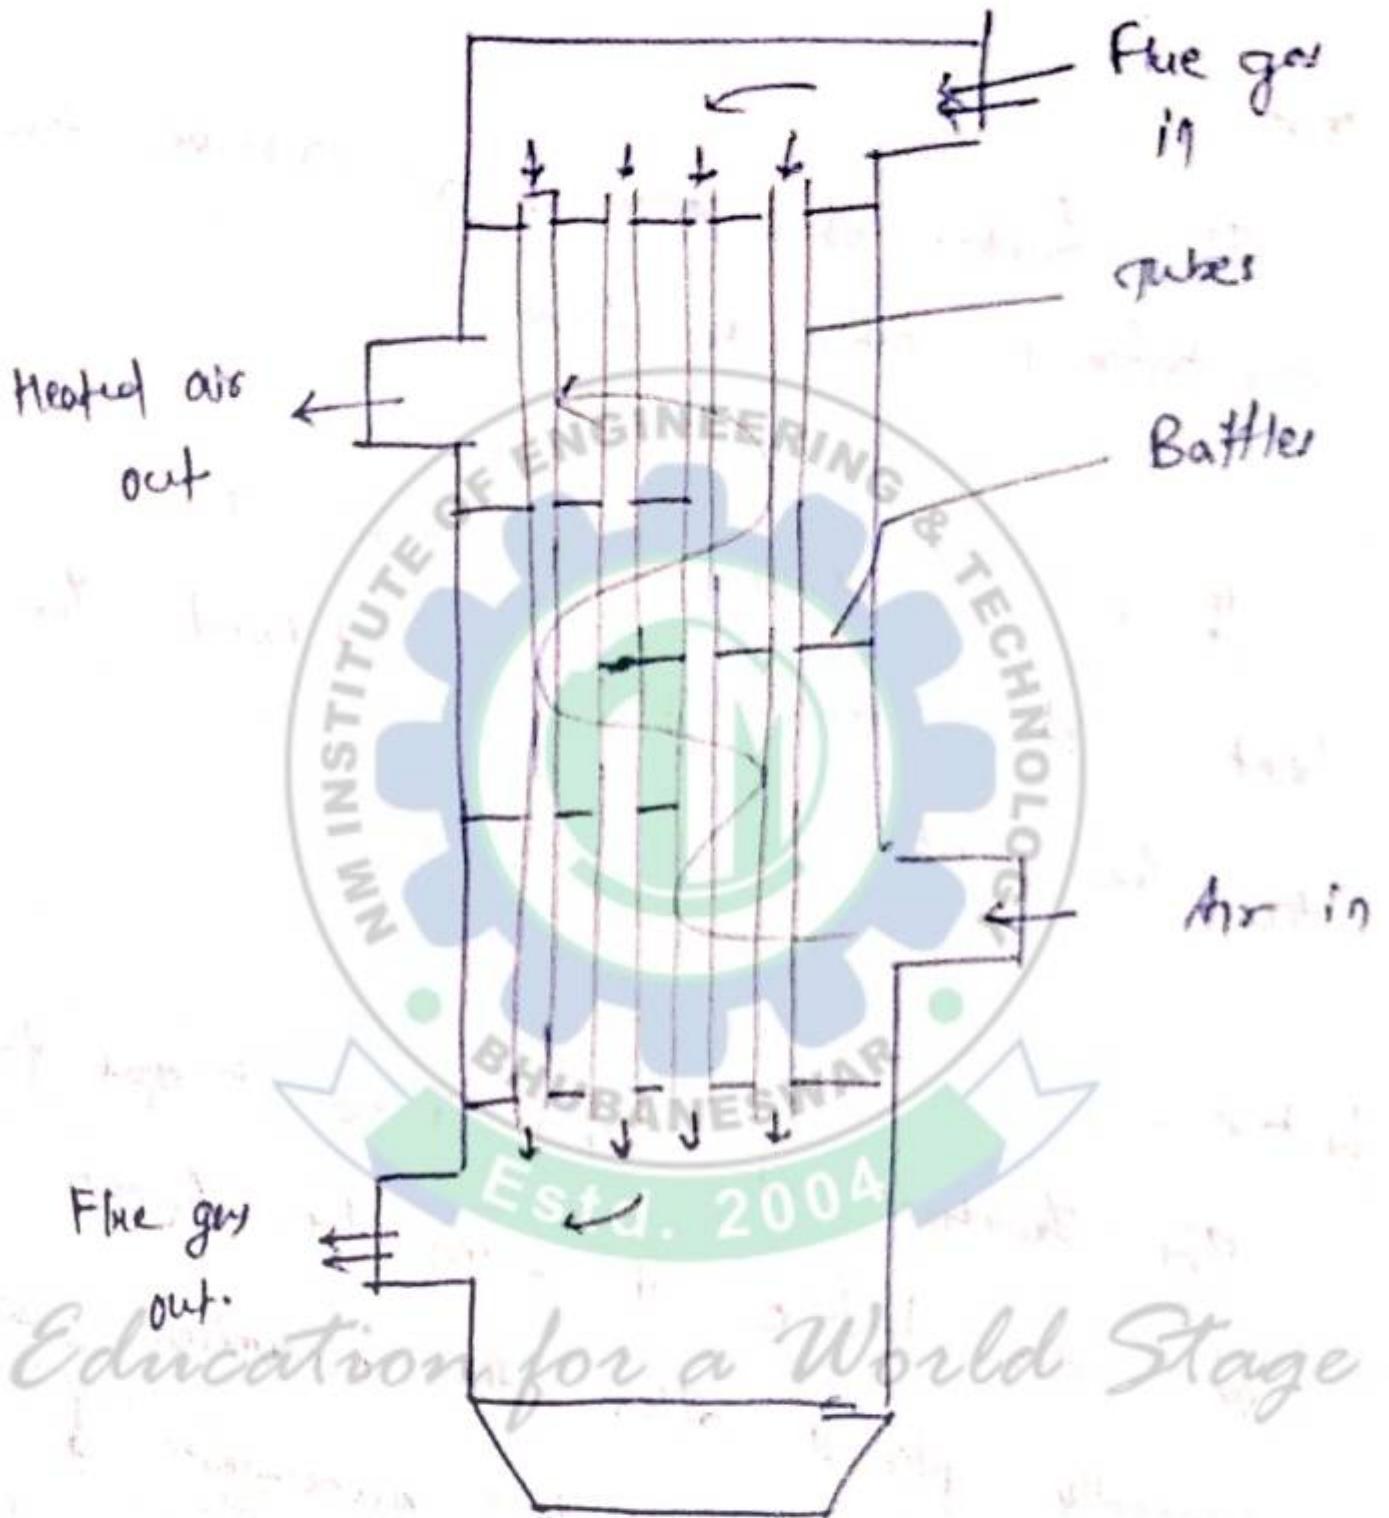

### Economiser

It is a device in which the waste heat of flue gases is utilised for heating the feed water.

### Air pre heater

The function of A.P.H is to increase the temp. of air before it enters the furnace.

It is generally placed after the economiser, so the flue gases pass through the economiser & then to the air preheater.

APH (Tubular type)

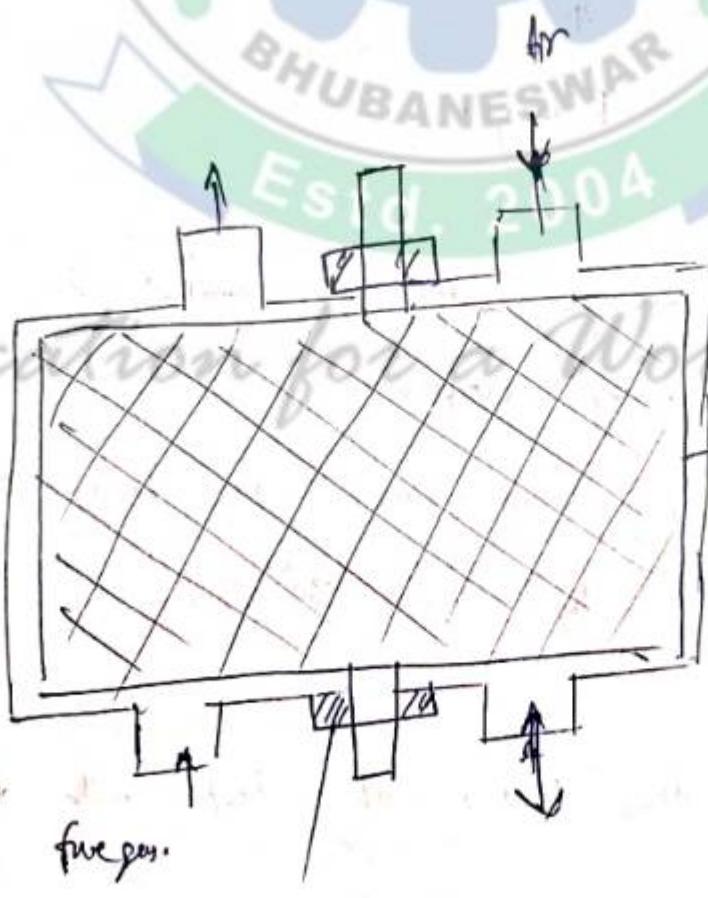

An APH consists of plates or tubes with hot gases on one side & air on another side. It preheats the air. Pre heated air accelerate the combustion & facilitate the burning of coal.

The pore heating depends on

- Type of fuel.
- Type of fuel burning equipment

3 types of APH

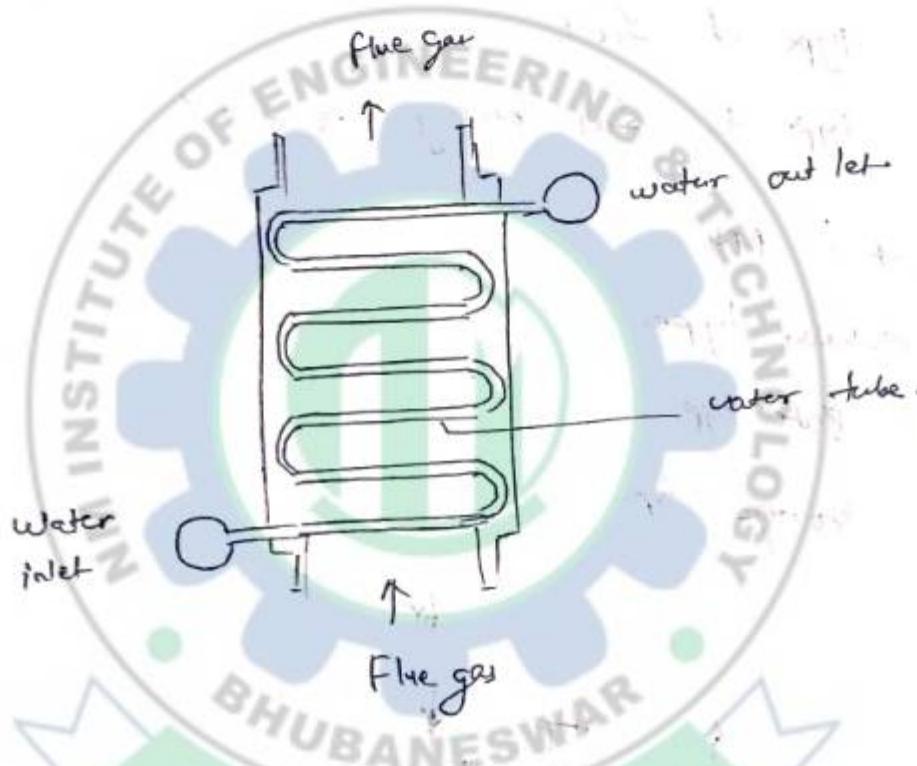

- 1) Tubular type
- 2) Plate type
- 3) Storage type

Rotor filled  
with wire mesh.

## Economiser

It is a device in which the waste heat of flue gas is utilised for heating the feed water.

In Steaming economiser water is raised to B.P.

10-12%. & water evaporates

In non-steaming economiser the temp. is kept

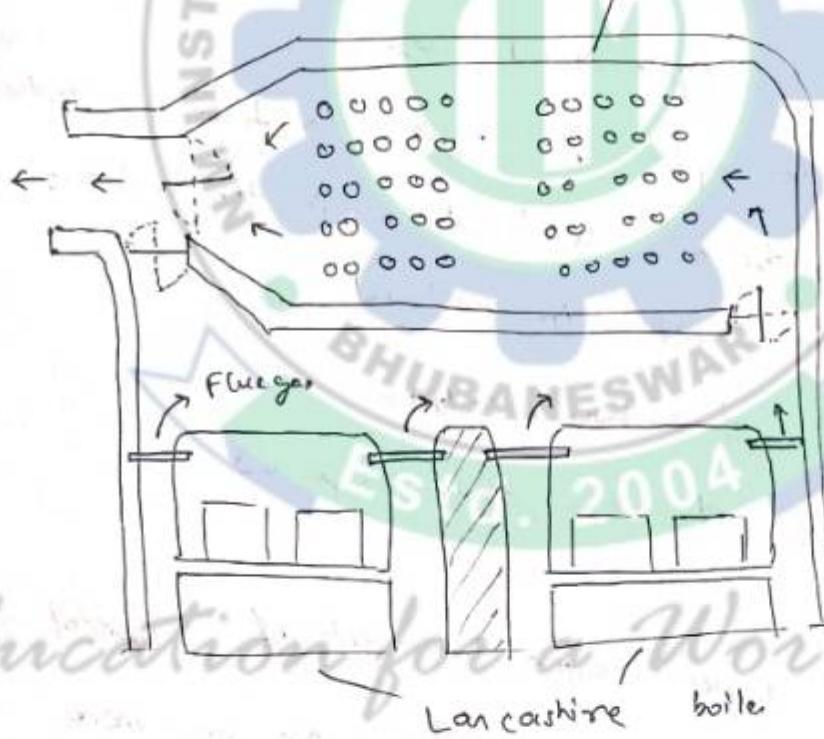

below B.P. by  $20 - 30^{\circ}\text{C}$ .

### Adv.

- i) Reduces the losses of heat with the flue gases
- ii) Reduces consumption of fuel
- iii) Improves efficiency of Boiler.

economiser consists of series of steel tubes through which the feed water flows. The combustion gases pass over the tube & transfer some of their heat to the feed water. The boiler efficiency rises by 1% for each  $10^{\circ}\text{F}$  rise in water.

Economiser may be parallel flow or counter flow.

(By pass arrangement of flue gas)

The by pass arrangement enables to isolate or include the economiser in the path of flue gas.

## Super Heaters :-

The steam produced in the boiler is nearly saturated. This steam as such should not be used in the turbine because the dryness fraction of the steam leaving the boiler will be low. This results in the presence of moisture which causes corrosion of turbine blades. The function of super heater is to increase the temp. of steam above its saturation point.

### Advantages of super heated steam :-

- i) Steam consumption of engine or turbine is reduced.
- ii) Losses due to condensation in the cylinders & the steam pipe are reduced.
- iii) Provision of turbine reduces.
- iv) Efficiency of power plant improved.

*education for a World Stage*  
The super heater consists of several tube circuits in parallel with one or more bends connected between headers. Super heater tubes range from 1 + 2 inches. in dia.

Super heater supplies steam at constant temp. at diff. loads.

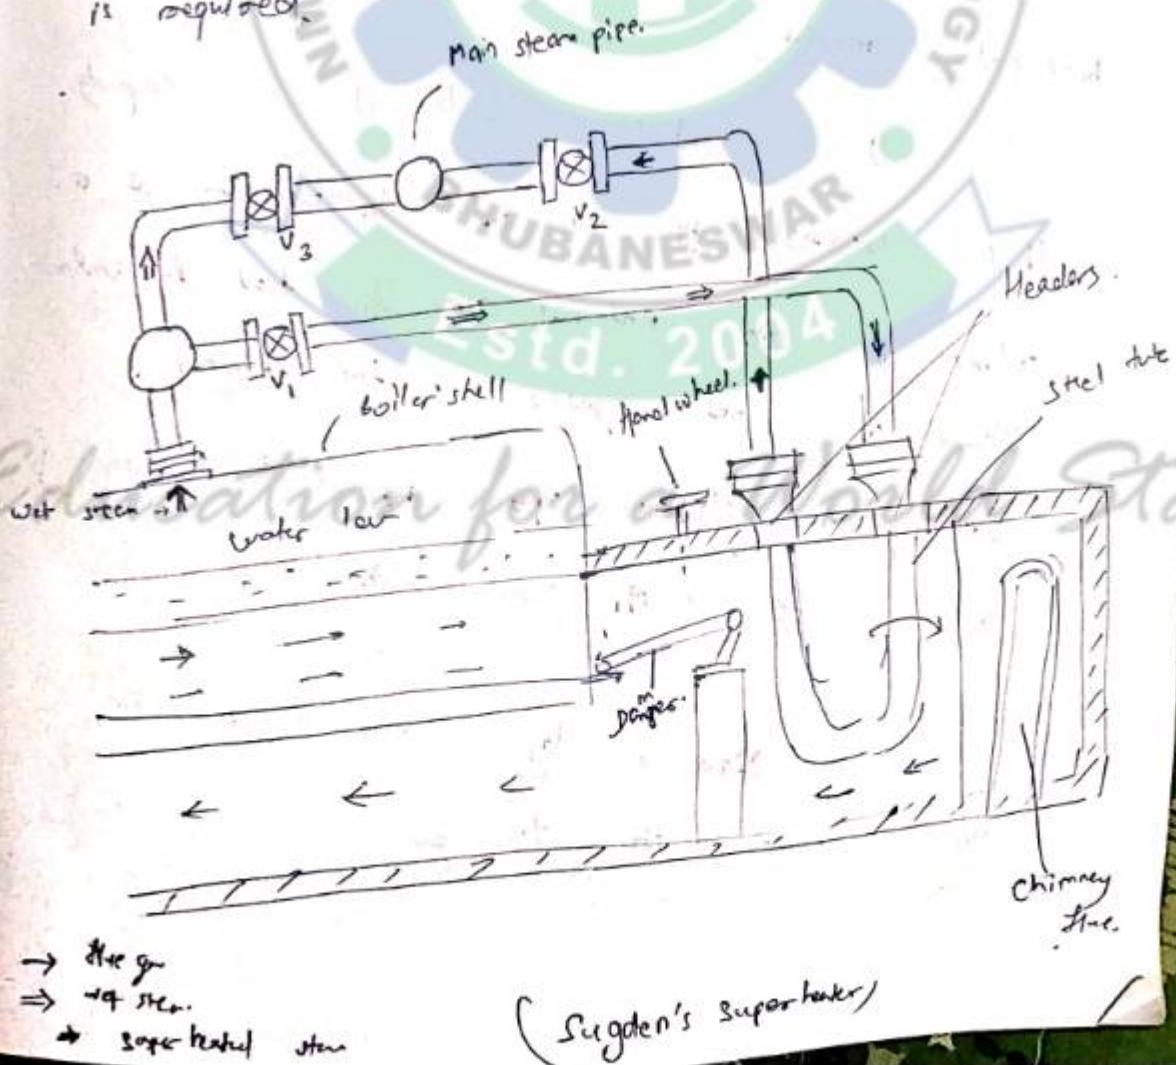

There are 2 types of superheater

1. Convective superheater
2. Radiant superheater.

Convective superheater makes use of heat in the gases alone.

Radiant superheater is placed in the furnace & coil tubes receive heat from the burning fuel through radiation process.

The radiant type of superheater is generally used where a high amount of superheat temp. is required.

## Draught

The small pr. difference which causes a flow of gas to take place is termed as draught.

### Purpose

- i) to supply req. amount of air to the furnace for the combustion of fuel.
- ii) to remove the gaseous products of combustion.

### Natural draught

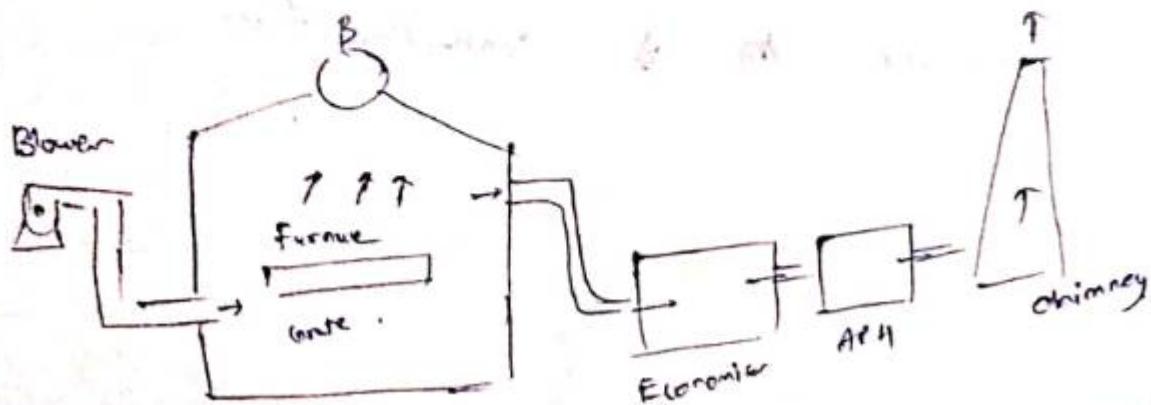

It is used in boiler of small capacity. It is created by the diff. in weight of a column of cold external air & that of similar column of hot gases in the chimney. This system depends upon height of chimney & temp. of gases in the chimney.

Now a days chimney is used for removing the fume gas.

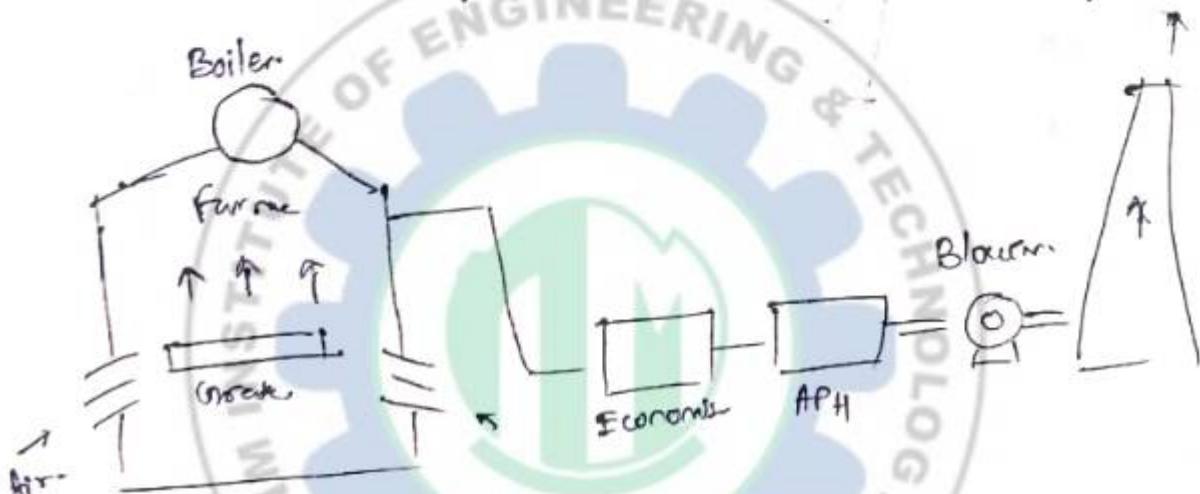

forced draft :-  
In a mechanical draft system the  
draught is produced by a fan. In a forced  
draught system a blower or a fan is  
installed near or at the base of boiler  
to force air through the coil bed  
of passage through the furnace.

*Education for a World Stage*

## Induced draft

In this system a fan or blower is located near the base of chimney. Partial vacuum is created in the furnace. Air is drawn from atmosphere to the furnace. The draft draught is similar in action to the natural draught.

## Balanced draft

It is a combination of forced draft and induced draft system. The forced draft FD fan overcomes the resistance in the APT and the induced draft ID fan overcomes draft losses through boiler, economiser, APT & connecting flues.

## Advantages of Mechanical Draft

- i) Easy control of combustion & evaporation.
- ii) Increase the evaporative power of boiler.
- iii) Improve efficiency.
- iv) Reduce chimney height.
- v) Prevention of smoke.
- vi) Capability of consuming low grade fuel.
- vii) High draft.

## Advantages of forced draft over induced draft

- i) FD fan does not require water cooled bearings.
- ii) Tendency to air leak into the boiler furnace is reduced.
- iii) No loss due to inrush of cold air through the furnace door.
- iv) FD fan handles cold air to fan size is  $1/5$  to  $1/2$  of ID fan.

## Moving parts

The steam turbine is a prime mover in which the P.E. of steam is transformed into K.E. and its form is transferred in to mechanical energy (rotation of turbine shaft)

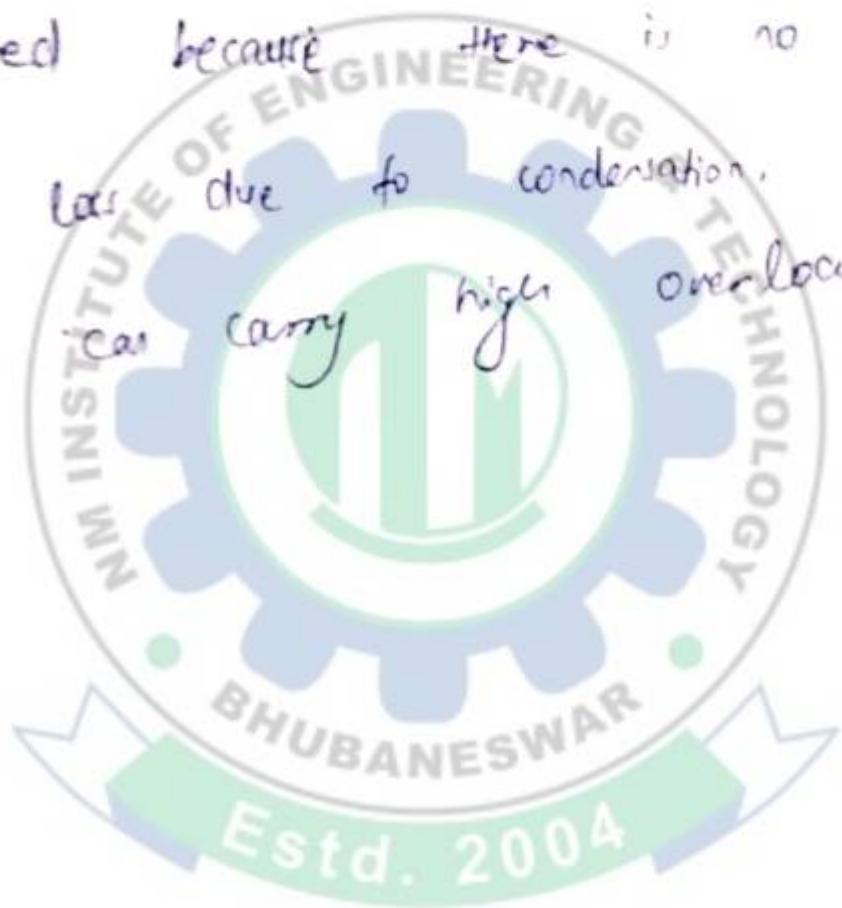

- 1) The main parts are :-
  - i) Rotor. The rotor is fitted with a series of blades on its circumference.
  - ii) Bearing to support the shaft.
  - iii) Metallic casing which surrounds blades, nozzles, rotor.
  - iv) Governor to control speed.
  - v) Lubricating oil system.

## Advantages :-

### Education for a World Stage

- i) The thermal efficiency is higher.
- ii) Power generation is uniform. (constant)
- iii) Much higher speed is possible.
- iv) Large thermal stations can be installed.
- v) Balancing problem is minimized because of no reciprocating parts.

- iv) Internal lubricating is not required because there is no rubbing parts
- v) No loss due to condensation.
- vi) It can carry high load.

Education for a World Stage

## Hydel Power Plant

### Hydro-electric Power Plant

The energy of water is utilized to move the turbines which runs the electric generator. The kinetic & potential energy of water is utilized to generate power.

Eg) Hirakud dam

Catchment area -  $83400 \text{ km}^2$  ( $32201^2 \text{ mile}^2$ )

Turbines - Kaplan type

Power = Total  $347.5 \text{ MW}$

Burha = P.H I =  $2 \times 49.5, 3 \times 37.5, 2 \times 32 \text{ MW}$

Chipling = P.H II =  $3 \times 24 \text{ MW}$

Started 1957

Cost = 1.01 billion Rs.

Type of dam = Composite dam & reservoir

Height =  $60.96 \text{ m}$

Length =  $4.8 \text{ Km}$  (main section)

$25.8 \text{ km}$  entire dam.

Spillways = 64 slice-gates, 34 coast-gates

Spillway capacity =  $42450 \text{ m}^3/\text{second}$ .

## Advantages of Hydro-electric Plants

- 1) No fuel charges.
- 2) It is highly reliable.
- 3) Maintenance & operation charges are very low.
- 4) Running cost is low.
- 5) The plant has no stand by losses.
- 6) The plant efficiency does not change with age.
- 7) It takes a few minutes to run & synchronise the plant.
- 8) Less supervising staff is required.
- 9) No fuel transportation problem.
- 10) There is no pollution.
- 11) Used for flood control & irrigation purposes.
- 12) Long life (100 - 125 years) but thermal plants: 20-45 yr
- 13) No. of operations required is small as compared to thermal plants.
- 14) The m/c runs at low speed so there is no mechanical problems.
- 15) No special alloys are required.
- 16) It is away from developed area so land cost is low.

## Dis-advantages :-

- 1) Initial cost of plant is high.
- 2) It takes long time to construct.
- 3) Such plants are away from load centre, so transmission line cost & losses is high.
- 4) The power developed is dependent on the quantity of water (weather).

## Classification

A. According to availability of head.

- 1) High head power plant
- 2) Medium head "
- 3) Low head "

B. According to the nature of load.

- 1) Base load plant

- 2) Peak load.

C. According to the quantity of water available

- 1) Run-of-river plant without pondage

- 2) Run-of-river plant with pondage

- 3) Storage type plants.

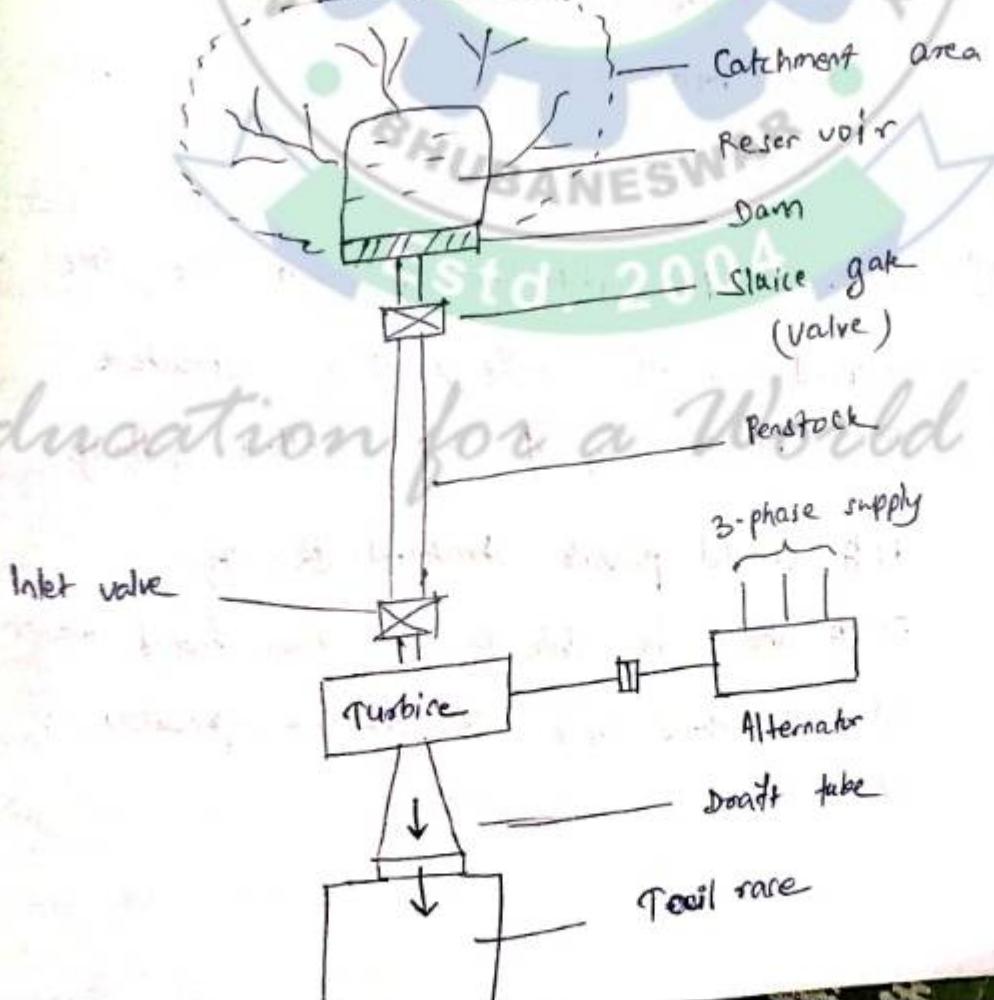

- 4) Pump storage plants

- 5) Mini & micro-hydro plants.

## Essential features of Hydro-electric power plant

1. Catchment area
2. Reservoir
3. Dam
4. Spill ways
5. Conduits
6. Surge tanks
7. Prime movers
8. Draft tubes
9. Power house & equipments.

Catchment area the whole area behind the dam draining into a stream or river across which the dam has been built at a suitable place is called catchment area.

Polymer It is employed to store water -

1. Natural Reservoir (lake)
2. Artificial " (It is built by dam)

Dam

It is a barrier to confine or retain water for storage or diversion to create a hydraulic head.

A. Fill dams

1. Earth dams
2. Rock-fill dams

B. Masonry dams

1. Solid gravity dam
2. Buttress dam
3. Arch dam

C. Timber dam

Spill ways - for stability of dam the excess water is relieved. This water passing structure provided in the body of dam is called spillways.

- i) It should provide structural stability
- ii) It should be able to pass the flood water.
- iii) It should have an efficient operation.
- iv) Economic.

## Type of spillways

1. Overfall / solid gravity spillway.
2. Chute / through spillway.
3. Side channel "
4. Saddle spillway.
5. Emergency "
6. Spill slot spillway.
7. Siphon spillway.

## Conduits:-

It is a channel which leads water to a turbine and a tailrace.

- 1) Open conduits → Canals, flumes
- 2) Close " → Tunnels, pipelines & penstock.

Canal - It is a open waterway excavated in natural ground.

Flume - It is an open channel erected on the surface supported above ground on a trestle. (frame)

Tunnel - It is a closed channel excavated through a natural obstruction such as ridge or higher land between the dam & power house.

Pipeline - It is a closed channel usually supported above the surface above the land.

Penstock :- It is a closed conduit for supplying water under pressure to a turbine.

Surge tank :-

It is a small reservoir or tank in which the water level rises or falls to reduce the pressure.

- It reduces the distance between the free water surface & turbine.
- It serves as a supply tank to the turbine & also a storage tank.

Types of surge tanks

1. Simple surge tank.

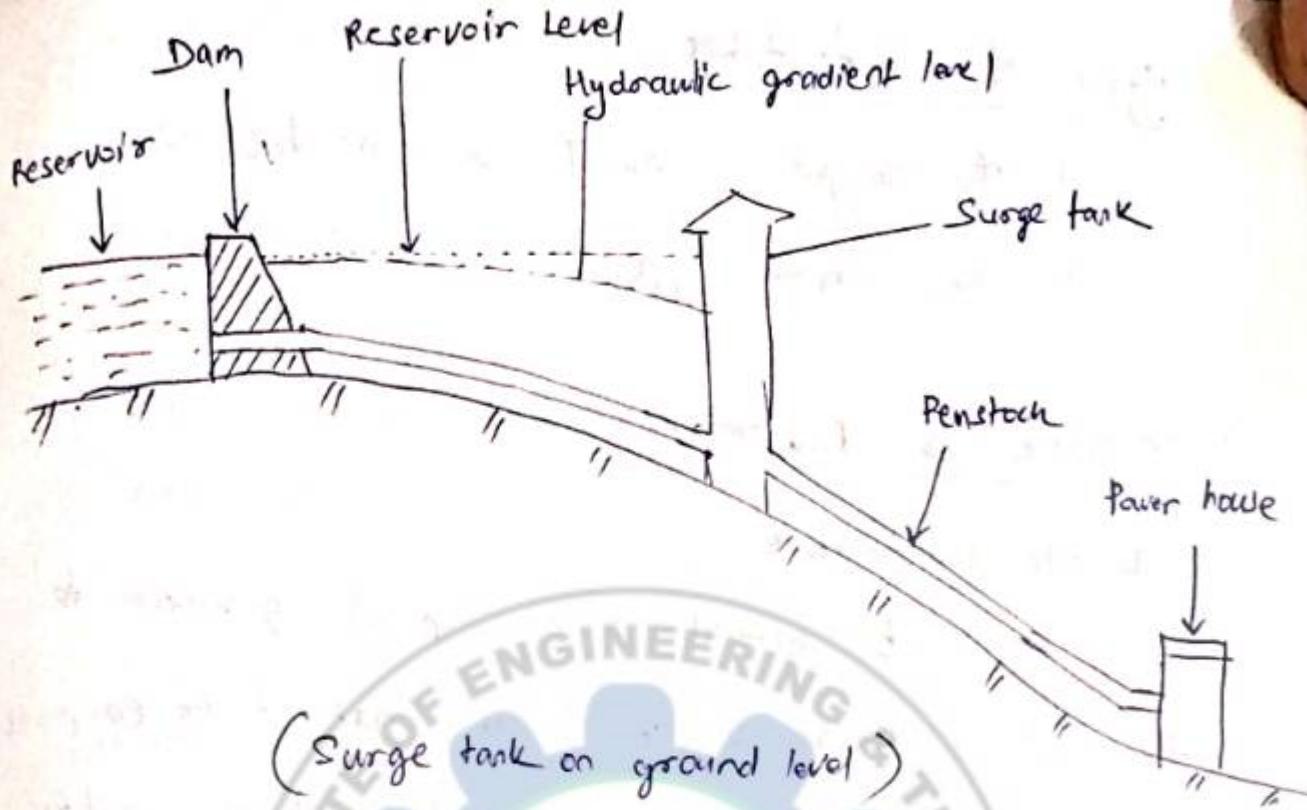

2. Inclined "

3. The expansion chamber & gallery type "

4. Restricted orifice surge tank.

5. Differential "

" ,

Prime movers :-

In an hydraulic power plant the prime mover converts the energy of water into mechanical energy & further into electrical energy.

1. Impulse turbine
2. Reaction turbine

Draft tubes :-

- It allows the turbine to be set above tail-water level with out loss of head to facilitate inspection & maintenance.
- It regains by diffuser action, the major portion of the K.E. delivered to it from the runner.

## Types of draft tubes:

- 1) The straight conical or concentric tube
- 2) The elbow type.

## Power House & Equipment

### 1. The Substructure:-

This part extends from top of generator to the soil or rock of it houses most of the equipment. In case of Francis & Kaplan turbine it accommodates the draft tube also.

### 2. Intermediate structure: It extends from top of the generator foundation to top of draft tube.

### 3. Super structure : If is above the generator level. It houses mostly cranes which handles heavy equipment.

i) Hydrodynamic turbines

ii) Electric generators

iii) Governors

iv) Gate valves

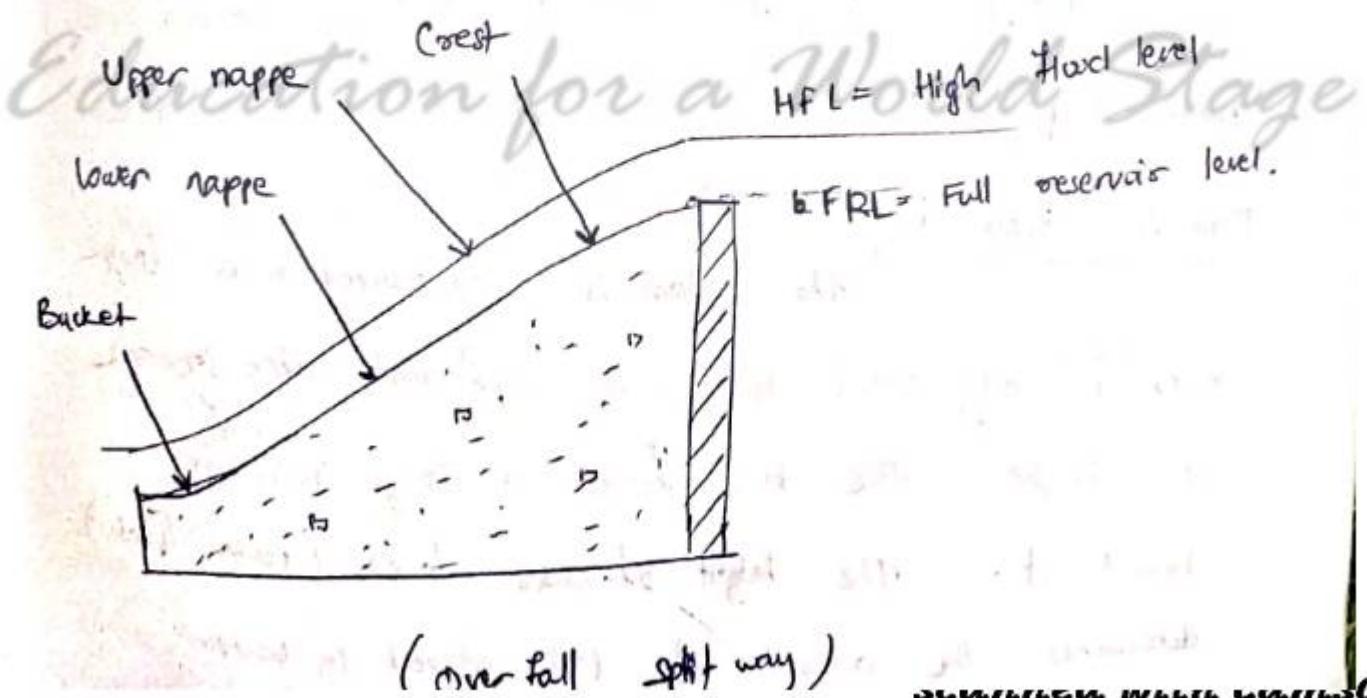

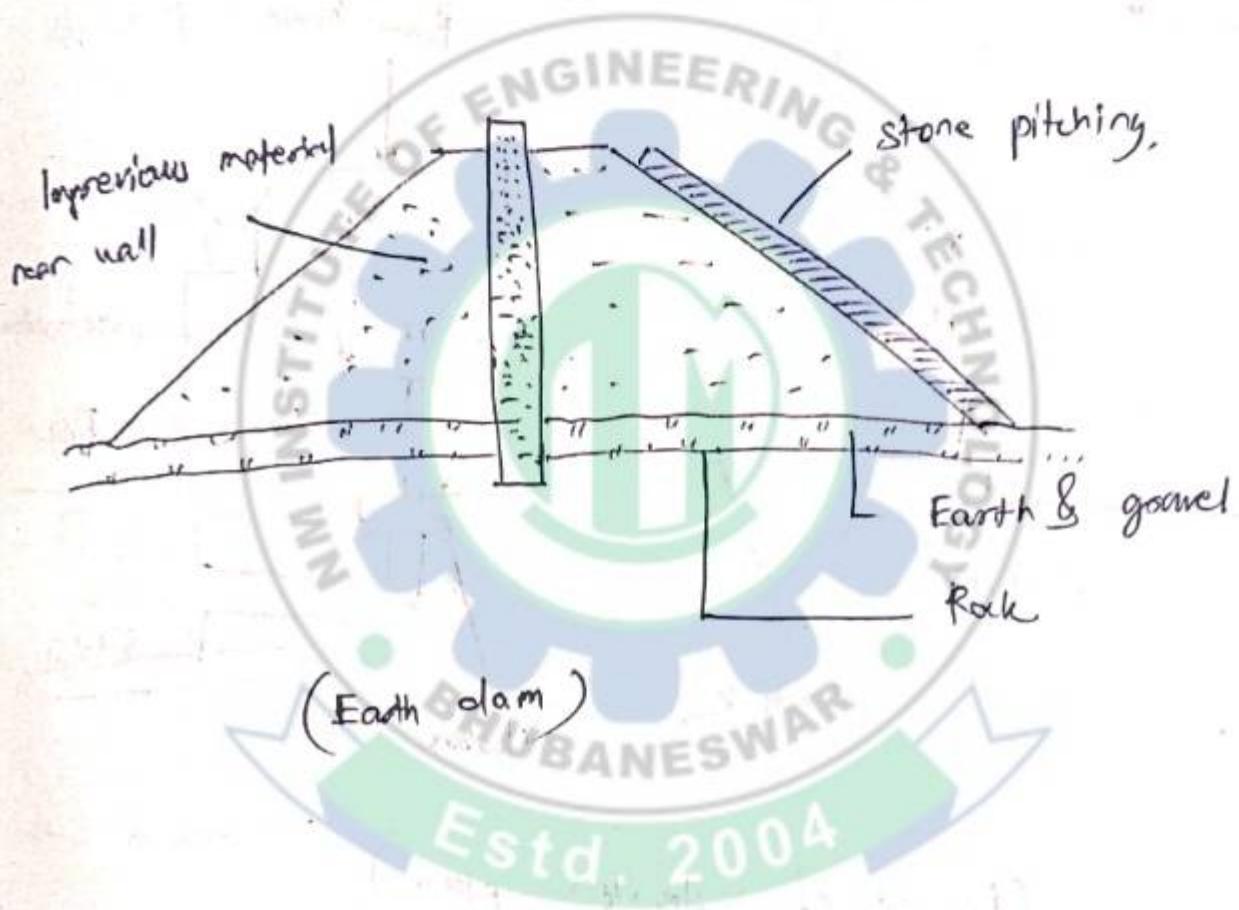

v) Relief valve

vi) Water circulating pump

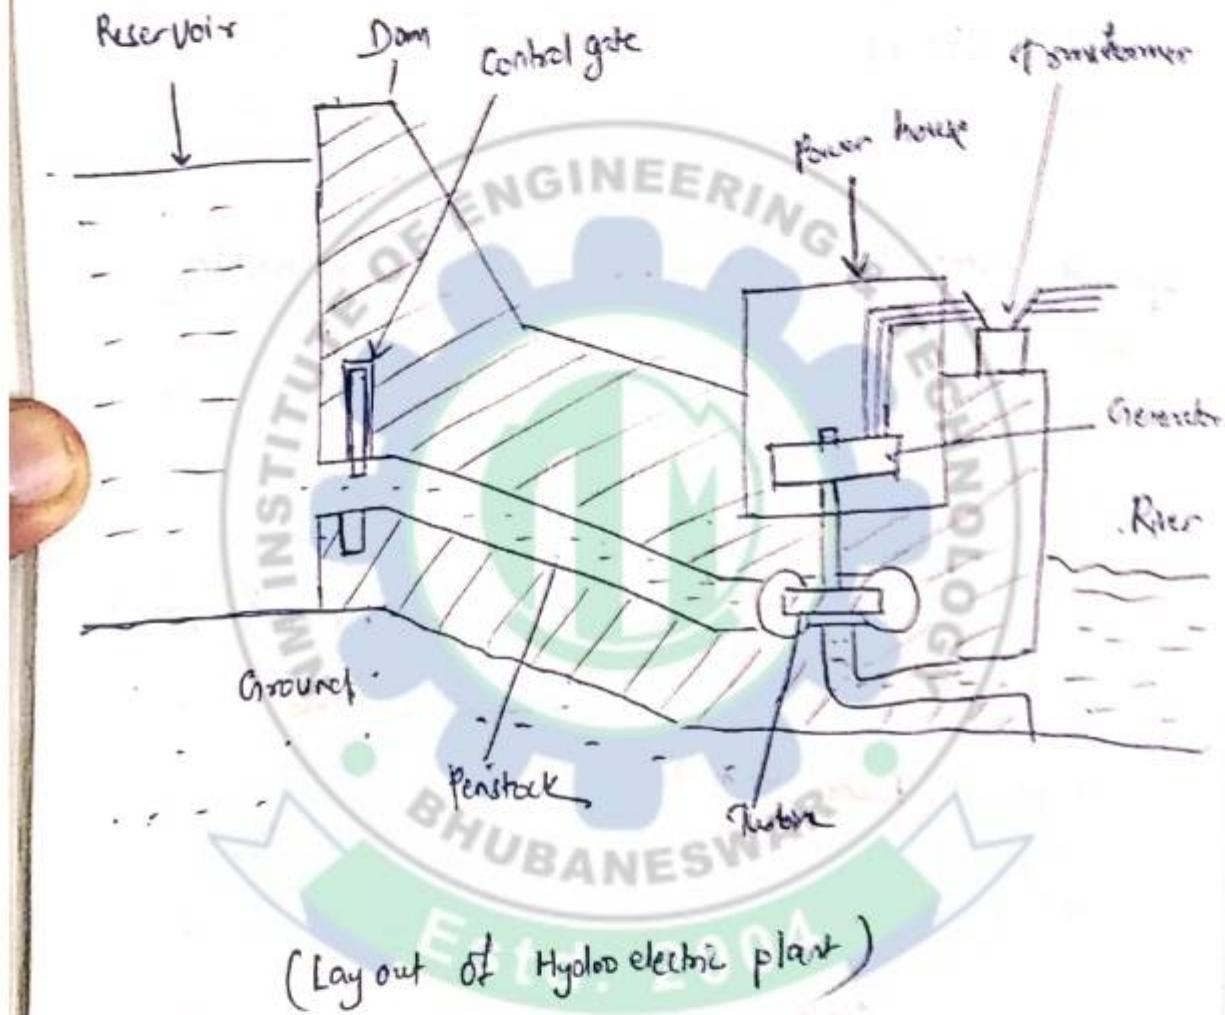

vii) Flow measuring equipments

viii) Air duct.

- v) Switch board equipments & instrument.
- vi) Oil circuit break
- vii) Reactors
- viii) Low tension & high tension bar.
- ix) Storage batteries
- x) Cranes.

General arrangement of storage type hydroelectric power plant & its operation.

Education for a World Stage

Dam & Reservoir

The dam is constructed on a large river in hilly areas to ensure sufficient water storage at height. The dam forms a large reservoir behind it. The height of water level (water head) determines the amount of P.E. stored in water.

### Control Gate

Water from the reservoir is allowed to flow through the penstock to the turbine. The amount of water that can be is to be released in

the penstock can be controlled by a control gate.

When the control gate is fully open, maximum amount of water is released through the penstock.

### Penstock

A penstock is a huge steel pipe which carries water from the reservoir to the turbine. P.E. of water is converted in to K.E. as it flows down through the penstock due to gravity.

### Water Turbine :-

Water from the penstock is taken into the turbine. Turbine is mechanically coupled to an electric generator. K.E. of water drives the

turbine and consequently the generator gets driven.

There are 2 main types of turbines

1) Impulse

2) Reaction

Impulse turbines are used for large heads.

Reaction turbines are used for low & medium head.

## Generator :-

A generator is mounted in the power house and it is mechanically coupled to the turbine shaft. When the turbine blades are rotated, it drives the generator and electricity is generated which is then stepped up with the help of a transformer for transmission purpose.

Generation of electricity by hydro power is one of the cleanest method of producing electricity. It is the most widely used form of renewable energy.

## DIESEL ENGINE POWER PLANT

A generating station in which diesel engine is used as the prime mover for the generation of electrical energy is known as Diesel engine power plant.

These are installed where supply of coal & water is not available in sufficient quantity, or where power is required in small quantity and stand by sets are required like hospitals, telephone exchanges, petrol pumps, radio stations etc.

Range = 2 to 50 MW.

### Advantages :-

### b) Applications

- Peak load plant

- Mobile plant

- Stand - by unit

- Emergency plant

- Nursery station

- Starting station

- Central station

- Industrial use.

## Advantages :-

1. Design & installation are very simple.
2. It can respond to varying loads without any difficulties.
3. Stand by losses are less.
4. Less space is required.
5. Can be started & put on load quickly.
6. It can also be designed for portable use.
7. It can be stopped quickly & easily.
8. Cooling system is easy & require less water.
9. Initial cost is less than other power station.
10. Thermal efficiency of its diesel is higher than co.
11. It requires less operating staff.
12. Overall cost is less.

*Education for a world Stage*

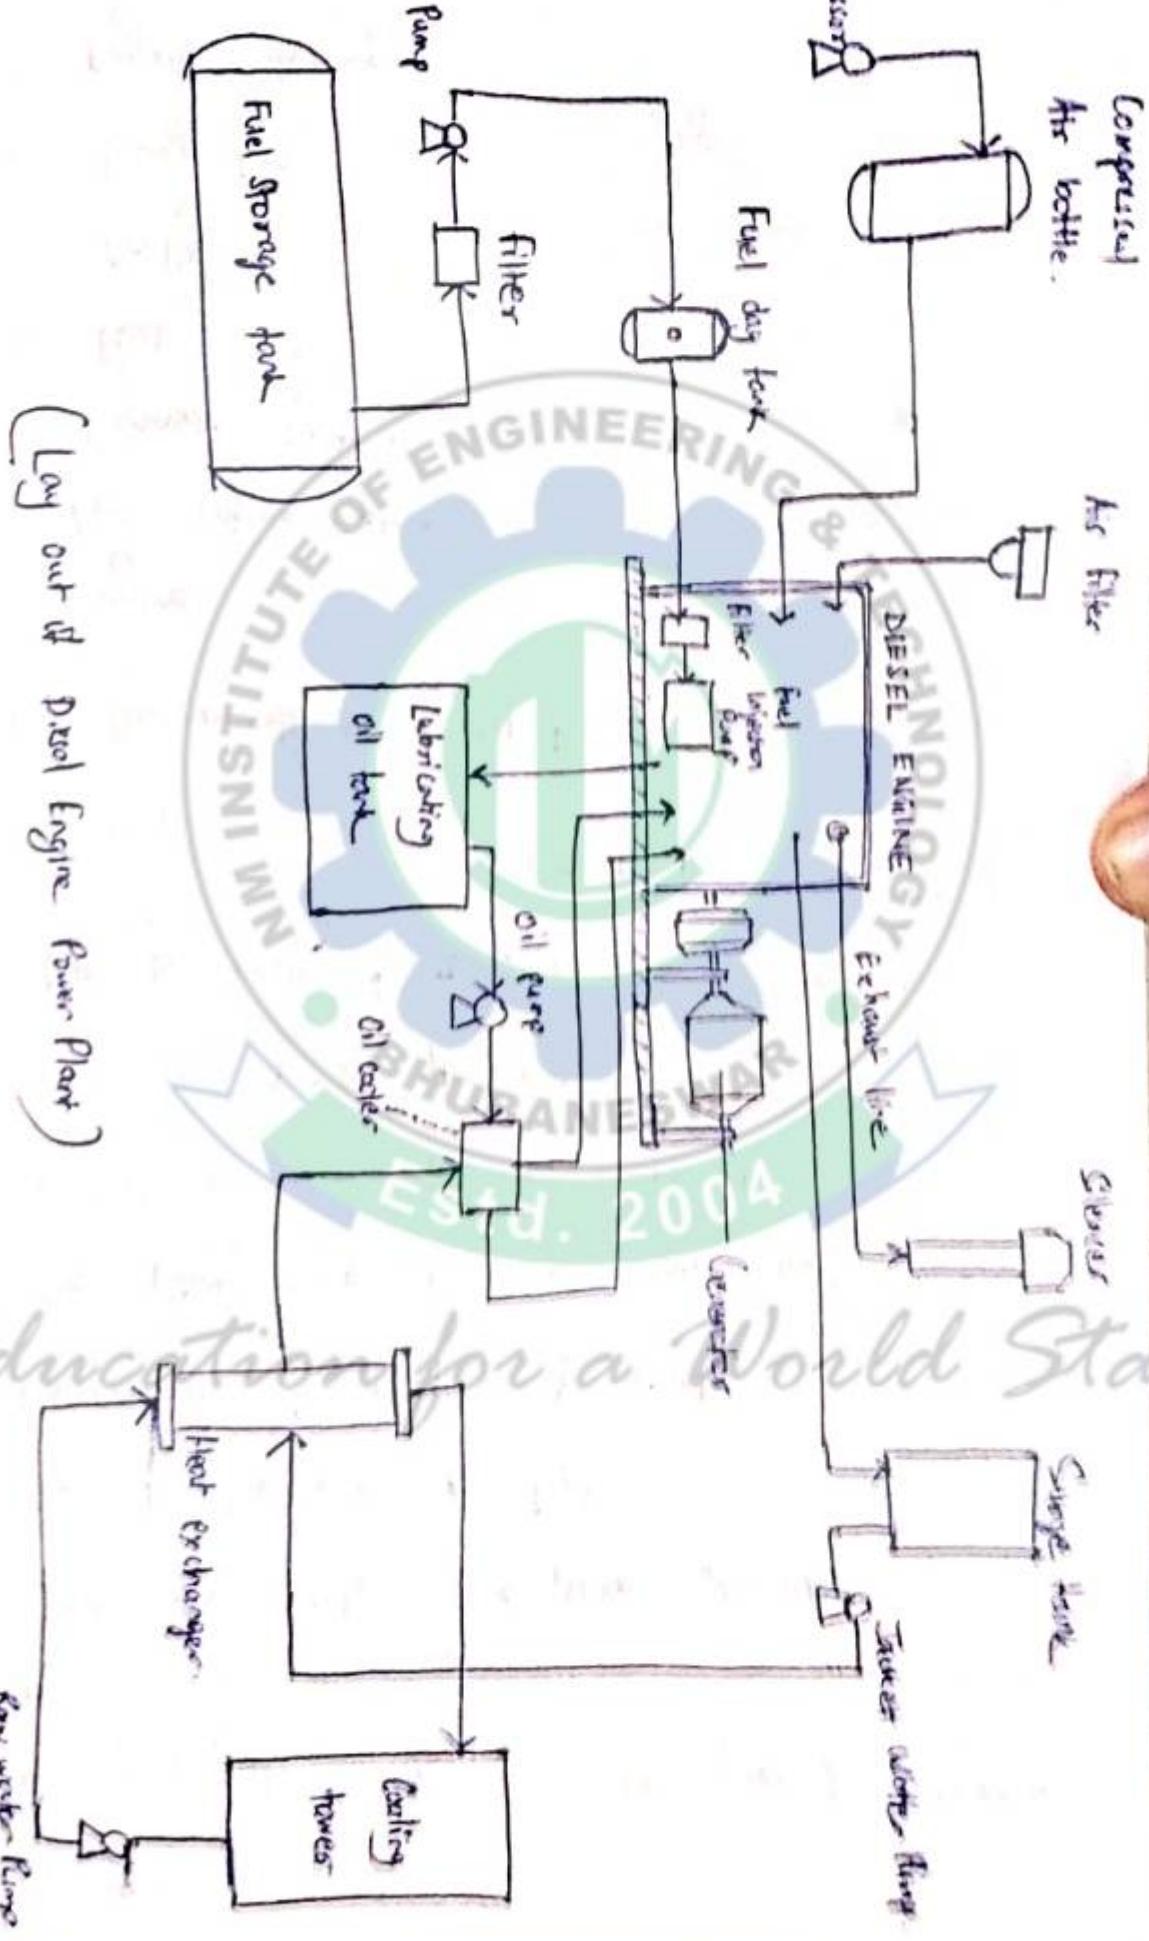

13. It can use wide range of fuels.
14. These plants can be located very near to the load centre.
15. No need of air handling.
16. Lubrication system is more economic.

### Disadvantages

1. Running costs high as the price of diesel is high.
2. Used for only small power generation.
3. Cost of lubricants is high.
4. Maintenance is complex & costly.
5. The plant does not work satisfactorily under over load condition for longer period.
6. Noise is a big problem.
7. Life is small (2 to 5 year) whereas  
(steam power plant 20 - 30 year)

### Essential Components of Diesel Power Plant

1. Engine
2. Air intake system
3. Exhaust system
4. Fuel
5. Cooling
6. Lubricating
7. Engine starting
8. Governing

Engine :- It is the main component of the plant which develops power. It is directly coupled with the generator.

2 types:- i) four stroke diesel engine.

ii) 2 " "

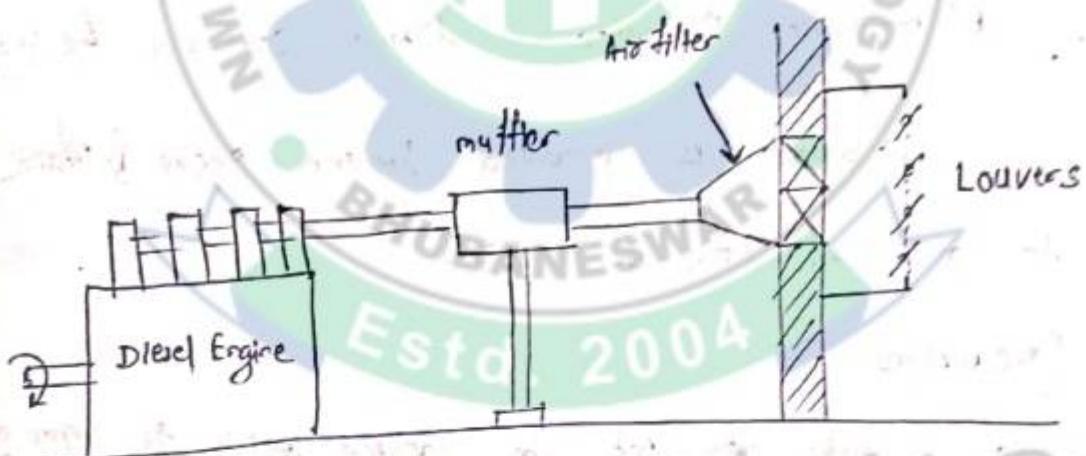

Air Intake system :-

It conveys fresh air to the

i) Air intake manifold of 4-stroke engines

ii) Scavenging pump inlet of a 2-stroke engine.

iii) Supercharger inlet of a supercharged engine.

*Education for World Stage*  
(Air Intake system)

The intake located out side the building provided with a filter to catch dust which would cause excessive wear in the engine.

Light weight steel pipe is used as inlet duct.

Many types of filters can be used.

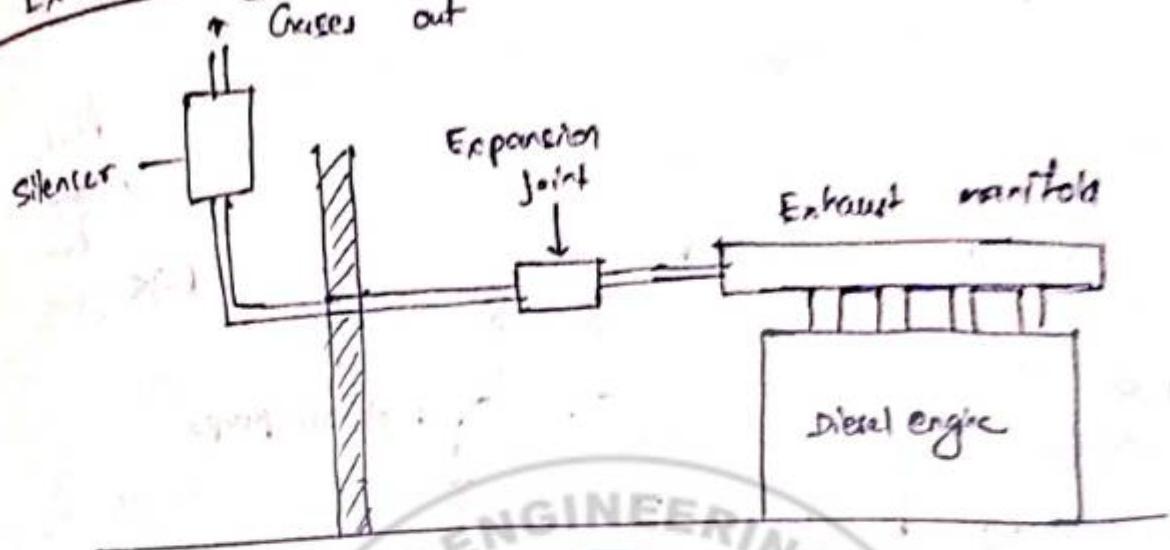

- Oil Impingement type of filter consists of a frame filled with metal shavings which are coated with oil so that the air passing through the ~~frame~~ frame can seize & hold the dust particles.
- The dry type filters are made of cloth, felt, glass wool etc.
- In oil bath type of filter the air is swept over through a pool of oil so that the particles of dust become coated.
- Electrostatic Precipitator filters can also be used.

Silencer is provided between engine & intake to arrest the noise of engine.

#### Precautions

- Air intake may not be located inside the engine room.
- Air should not be taken from a confined space.
- The air intake pipe should neither have small diameter nor large diameter.
- Air intake filter may not be located close to the engine room road..
- Air intake filter should not be located in an inaccessible location.

## Exhaust system :-

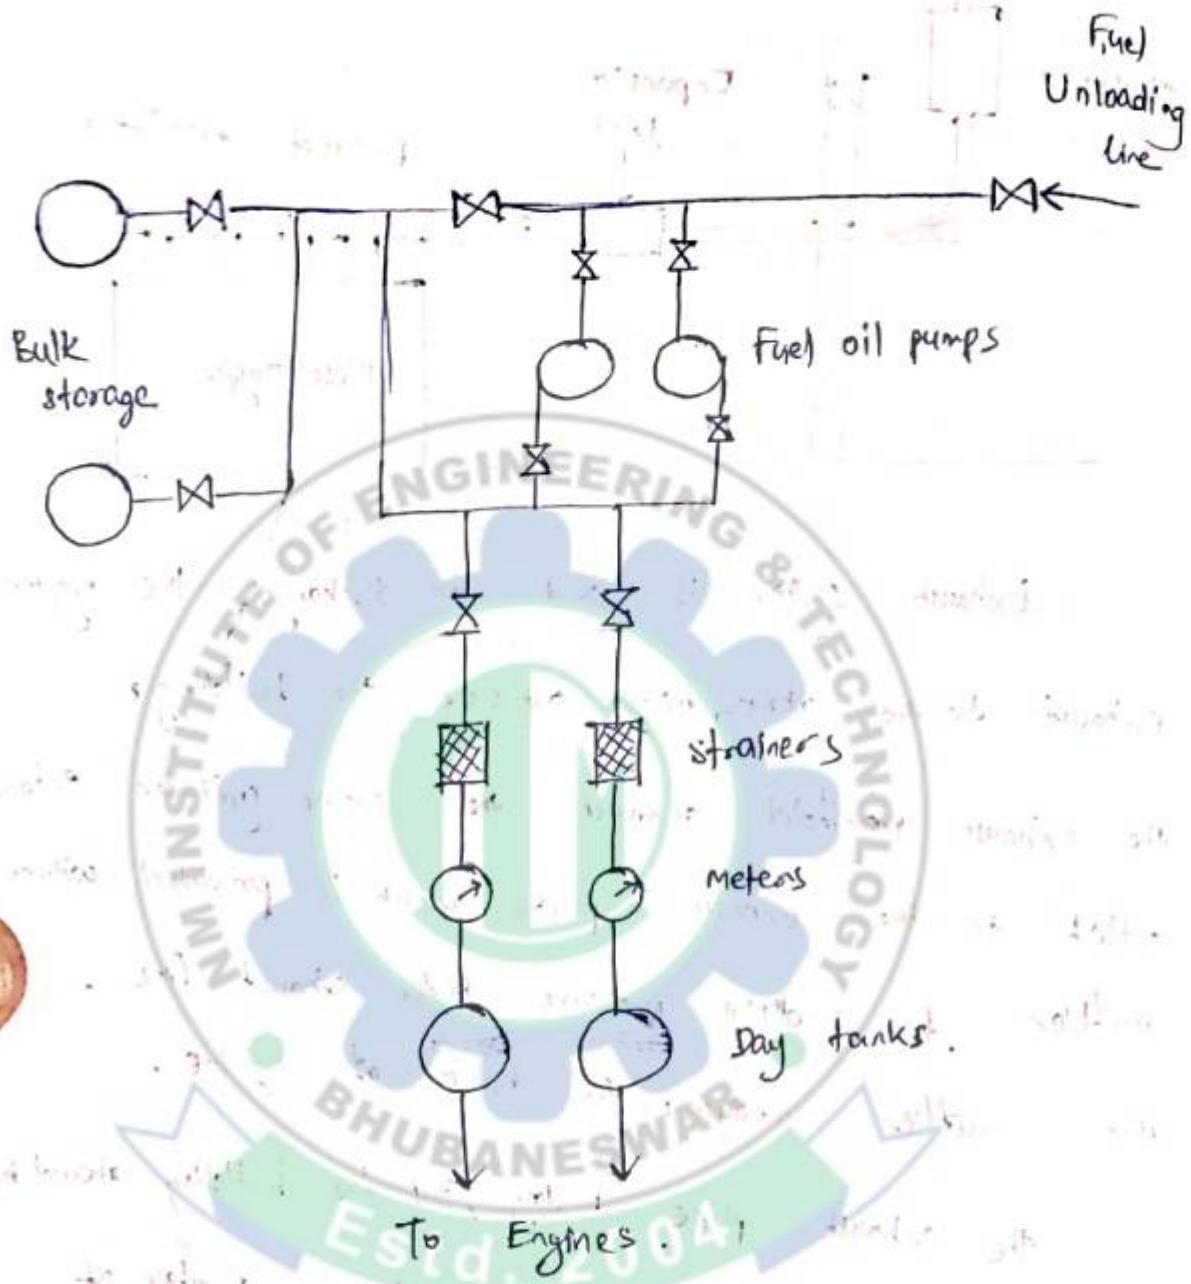

Exhaust system is used to discharge the engine exhaust to the atmosphere outside the building. The exhaust manifold connects the engine cylinder exhaust outlet to the exhaust pipe which is provided with a muffler to reduce pressure in the exhaust line. The muffler reduces the noise of engine.

The exhaust pipe leading out the building should be short in length with having minimum number of bends. It should have one or two flexible tubing sections which take up the effects of expansions & isolate the system from engine vibration.

Every engine should have its independent exhaust system.

## Fuel System

The fuel oil may be delivered at the plant site by tanks, railroad tank to the main storage tanks. Then it is transferred to the small storage tank called day tank.

the main flow line is arranged with necessary  
heaters, by-passes, shot with drain lines, relief  
valves, strainers & filters, flow meters, & temperature  
indicators.

The tank shell contains man-hole for internal access  
& repair, fill line to receive oil, vent lines to  
drainage tanks & one flow line.

At least one month's requirement amount of oil  
should be kept in the storage tank. The day  
tank provides daily need of oil to the engine.  
The day tanks are placed high so that oil may  
flow to engine under gravity.

- There should be clean lines & provided for pipelines.
- Changing over of lines during emergencies.
- In all suction lines the pipe joints should be made tight.
- Before covering the pipe lines should be tested
- through air pressure & joints should be tested by  
soap solution.
- Piping between filter & engine should be oil flueless.
- High grade filters should be used.

## Fuel Injection System :-

A very small quantity of fuel is measured, atomized and mixed with combustion air.

In diesel engine atomized fuel is sprayed in the cylinder under pressure usually ranging from approximately  $100 \text{ to } 120 \text{ kg/cm}^2$ .

### functions of fuel injection system :-

- filter the fuel.
- Meter or measure the correct quantity of fuel.
- Time the fuel injection.
- Control the rate of fuel injection.
- Authorise the fuel
- Properly distribute the fuel in the combustion chamber.

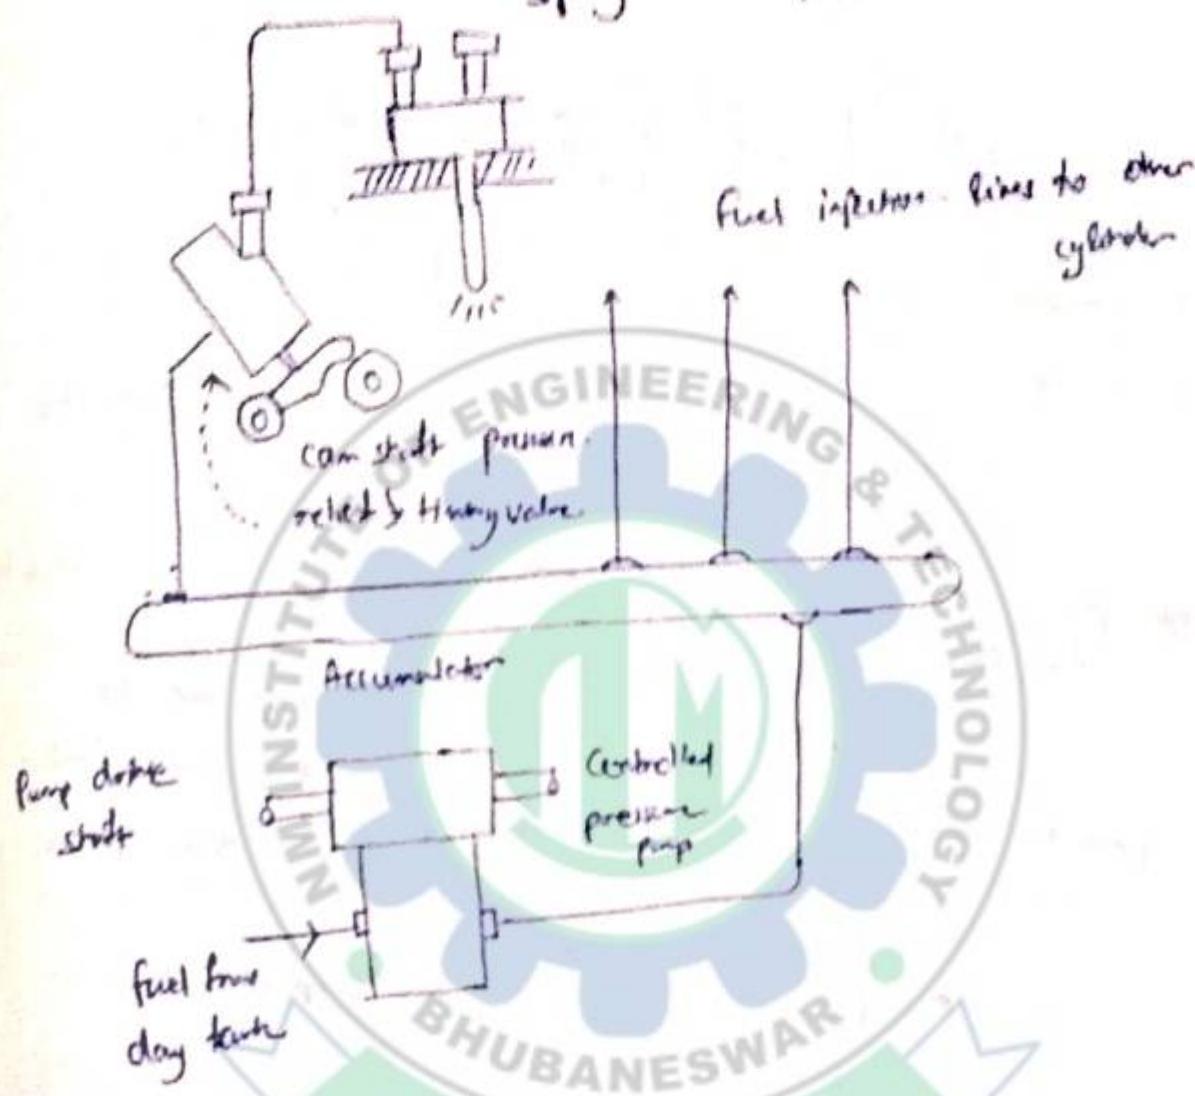

*Education for a World Stage*

### Types of fuel injection system

1. Common rail injection system
2. Individual pump
3. Distributor

Common rail injection

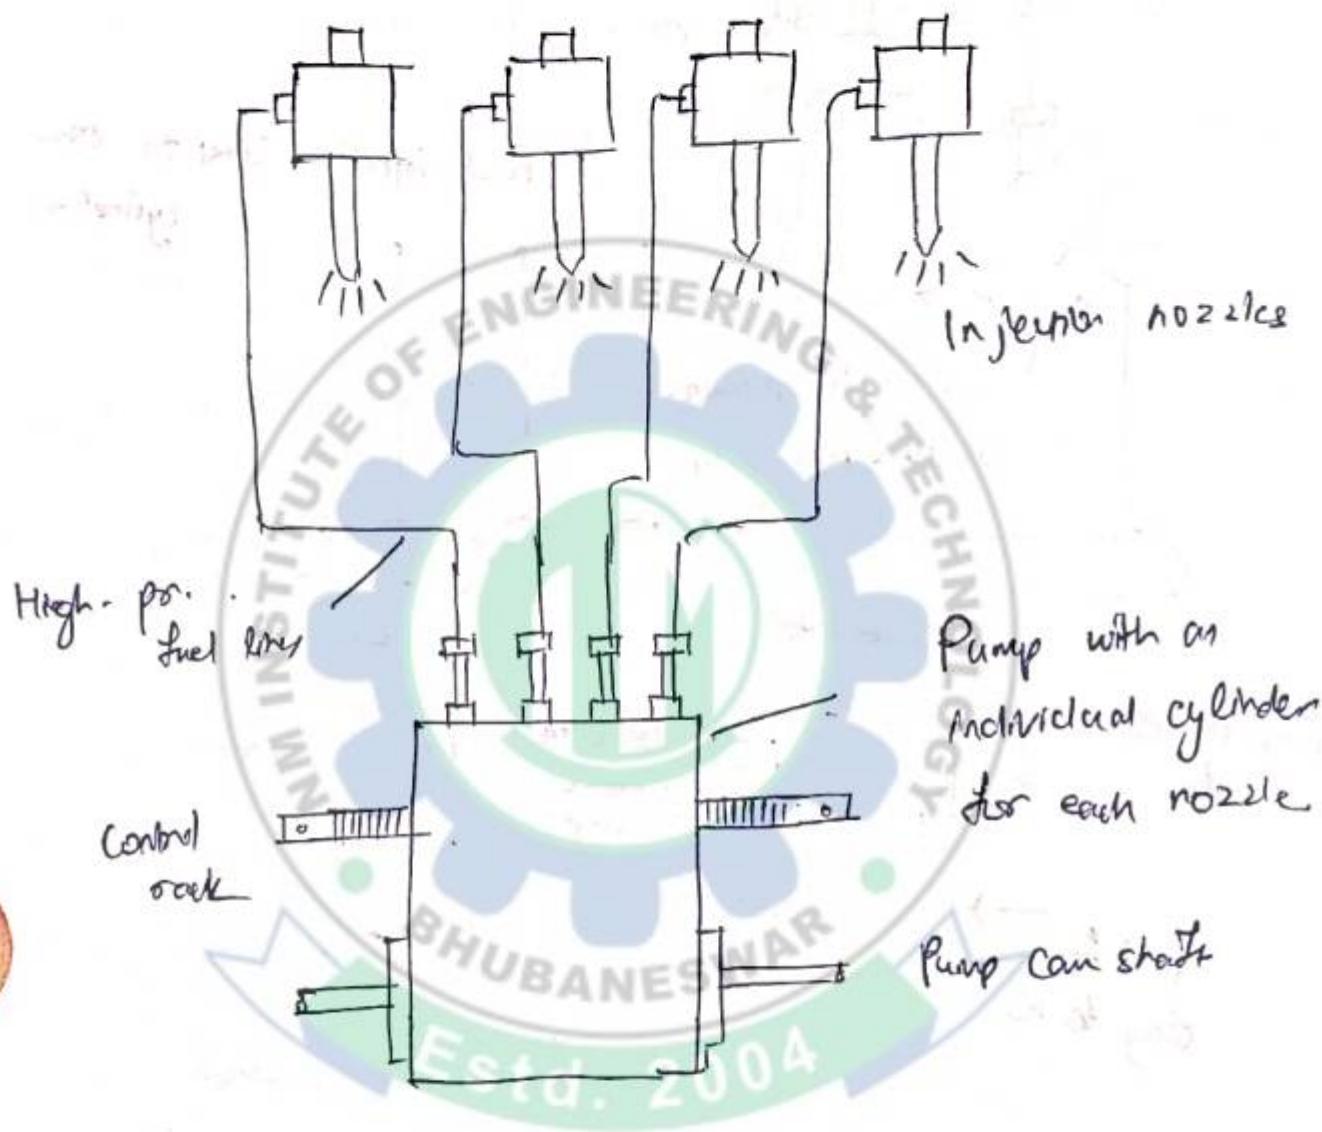

Spring loaded spray valve

A single pump supplies high pressure fuel to header, a relief valve holds pressure constant.

controlled pressure system has pump which maintains set head pressure. Valves regulate injector time & amount.

## Individual pump injection

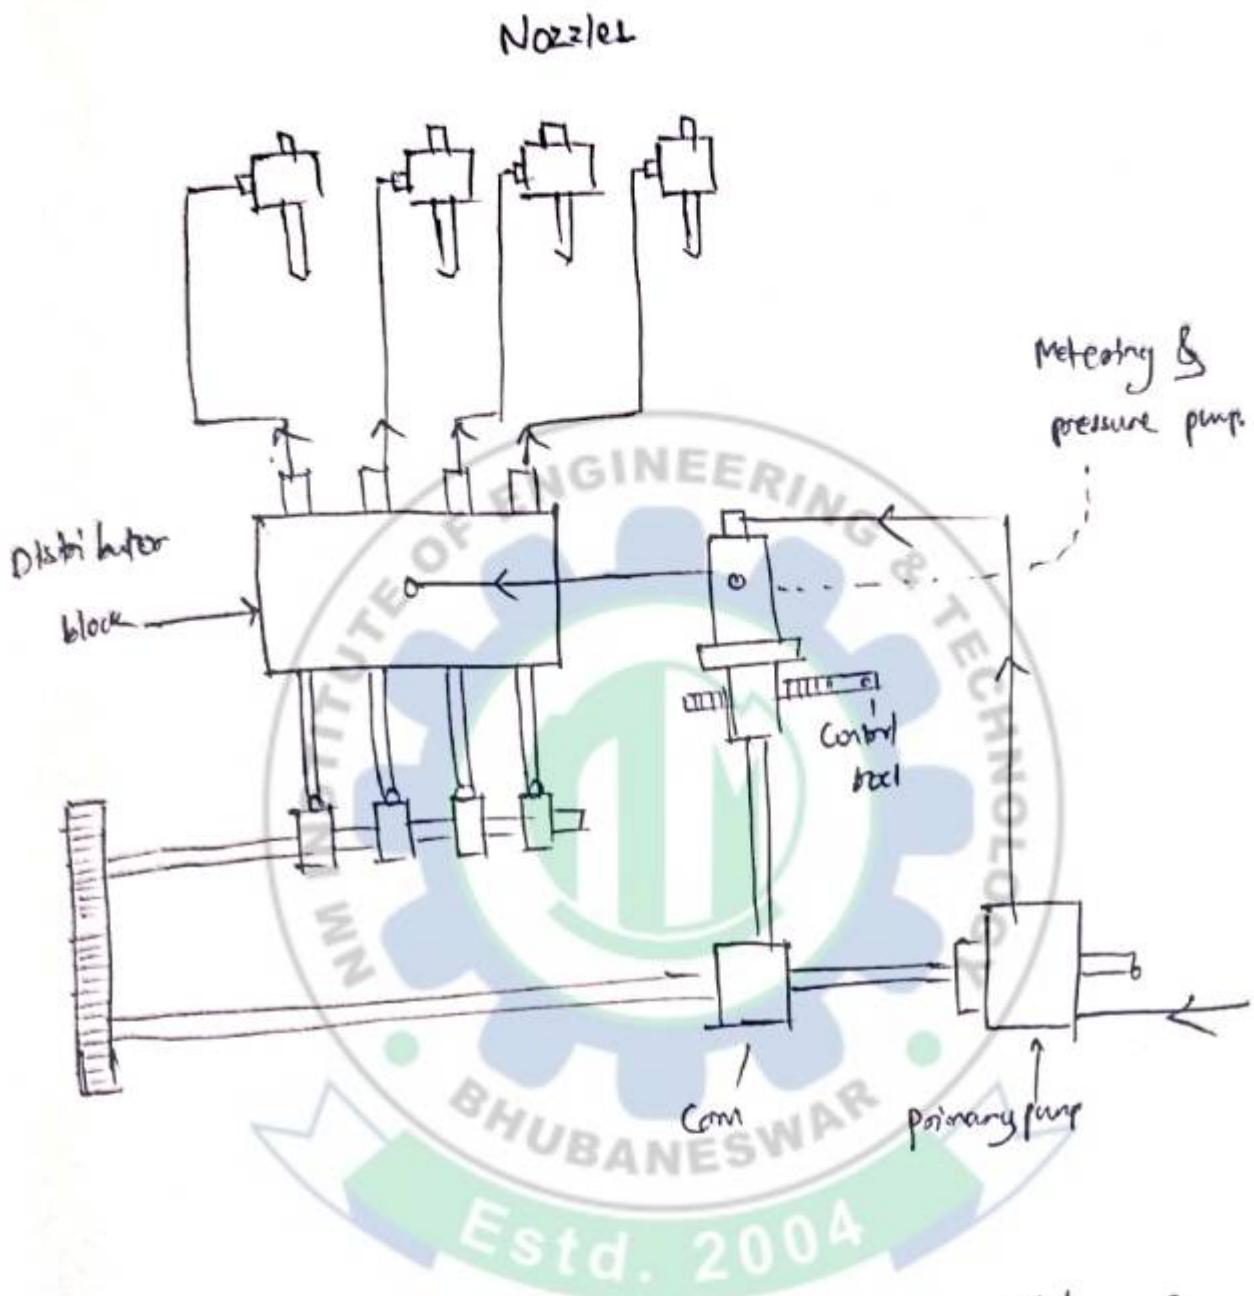

An individual pump or pump cylinder connects directly to each fuel nozzle.

Pump meter charge & control together timing.

Nozzle contains a delivery valve actuated by the fuel oil pressure.

## Distributor injection

The fuel is metered at a central point, a pump pressurizes the fuel & then the fuel enters the injection . from here ; the fuel is distributed to cylinders in correct firing order by cam operated poppet valves which open to admit fuel to the nozzles.
